Renormalising SPDEs in regularity structures

Abstract

The formalism recently introduced in [BHZ16] allows one to assign a regularity structure, as well as a corresponding “renormalisation group”, to any subcritical system of semilinear stochastic PDEs. Under very mild additional assumptions, it was then shown in [CH16] that large classes of driving noises exhibiting the relevant small-scale behaviour can be lifted to such a regularity structure in a robust way, following a renormalisation procedure reminiscent of the BPHZ procedure arising in perturbative QFT.

The present work completes this programme by constructing an action of the renormalisation group onto a suitable class of stochastic PDEs which is intertwined with its action on the corresponding space of models. This shows in particular that solutions constructed from the BPHZ lift of a smooth driving noise coincide with the classical solutions of a modified PDE. This yields a very general black box type local existence and stability theorem for a wide class of singular nonlinear SPDEs.

1 Introduction

This article is part of the ongoing programme initiated in [Hai14] aiming to develop a robust existence and approximation theory for a wide class of semilinear parabolic stochastic partial differential equations (SPDEs). The problem we tackle here is that of showing that when such equations are “renormalised” using the procedure given in [BHZ16, CH16], the resulting process is again the solution to a modified equation containing counterterms that only depend in a local way on the solution itself.

A similar situation to the one dealt with here already arises in the classical theory of stochastic integration. There, one is faced with the problem of defining integrals with respect to Brownian motion which, on a pathwise level, has insufficient regularity for the classical Riemann-Stieltjes integral to be well-defined. When establishing the convergence of discrete approximations one must take advantage...
of probabilistic cancellations in order to overcome this pathwise irregularity. Moreover, one sees that different classes of approximations that would have had the same limit for the case of regular drivers actually lead to different limiting integrals with different properties when working with irregular stochastic drivers – in the limit, one can obtain either the Itô or Stratonovich integral, or any of a one-parameter family of theories of stochastic integration which contains these as special cases [KPS04]. In practice this choice is informed either by phenomenological considerations or by a desire for the integral to satisfy a given mathematical property.

In the theory of parabolic, locally subcritical SPDEs, both the design of approximations and the framework for showing convergence of these approximations become more involved. A rigorous solution/integration theory in this case was fairly intractable until just a few years ago – now there are several frameworks available that provide rigorous descriptions of what it means to be a (local) solution to these SPDEs: the theory of regularity structures [Hai14], the theory of paracon-trolled distributions [GP13], a Wilsonian renormalisation group approach [Kup16], and most recently the approach of [OW16]. Although these approaches differ in their technical details and their scope of application, the solutions constructed with all of them do coincide for those examples in which more than one approach applies.

As an example, suppose that one wants to develop a notion of solution for the Cauchy problem associated to the system of SPDEs on $\mathbb{R}^+ \times \mathbb{T}^d$

$$\left(\partial_t - \Delta\right)\varphi_j = F_j(\varphi, \nabla \varphi) + \xi_j, \quad (1.1)$$

where $(F_j)_{j=1}^m$ is a collection of local non-linearities given by smooth functions. One can take the vector of “drivers” $\xi = (\xi_j)_{j=1}^m$ to be a family of generalised random fields which are stationary, jointly Gaussian, and have covariances $E[\xi_j(z)\xi_k(\bar{z})]$ which are smooth as long as $\bar{z} \neq z$ but behave like a homogeneous distribution of some negative degree near the diagonal $z = \bar{z}$. A sufficient condition for (1.1) to be locally subcritical is that, via power-counting considerations, the non-linear term $F_j(\varphi, \nabla \varphi)$ is expected to be of better regularity than the driving noise $\xi_j$.

In many cases of interest one cannot solve (1.1) using classical deterministic methods since the lack of regularity of $\xi_j$ may force some $\varphi_j$ to live in a space of functions/distributions on which $F_j(\varphi, \nabla \varphi)$ has no canonical meaning. A naive way to obtain a well-defined approximation to (1.1) is to replace $\xi_j$ with $\xi_j^{(\varepsilon)} = \xi_j * \theta_{\varepsilon}$ where $\varepsilon > 0$ and $\theta_{\varepsilon}$ is a smooth approximation of the identity with $\lim_{\varepsilon \to 0} \theta_{\varepsilon} = \delta$. Then one has classical solutions $\varphi_{\varepsilon} = (\varphi_{j,\varepsilon})_{j=1}^m$ for the system of equations

$$\left(\partial_t - \Delta\right)\varphi_{j,\varepsilon} = F_j(\varphi_{\varepsilon}, \nabla \varphi_{\varepsilon}) + \xi_j^{(\varepsilon)}, \quad (1.2)$$

Unfortunately, in the generic situation, $\varphi_{j,\varepsilon}$ will either fail to converge as $\varepsilon \downarrow 0$, or converge to a trivial limit as in [HRW13], so that simply replacing $\xi_j$ with $\xi_j^{(\varepsilon)}$ does not allow one to define solutions to (1.1) via a limiting procedure.

Upon studying the $\varepsilon \downarrow 0$ behaviour of formal perturbative expansions for $\varphi_{\varepsilon}$, one is naturally led to a more sophisticated approximation procedure. In general, one

---

1See Definition 2.2 and the remark following it for a formal definition.
expects to find \( n_1, \ldots, n_m \in \mathbb{N} \) and, for each \( j = 1, \ldots, m \), a family of constants \( \{ c_{j,i}(\varepsilon) \}_{i=1}^{n_j} \), typically divergent as \( \varepsilon \to 0 \), as well as a family of functions \( \{ P_{j,i}(\cdot, \cdot) \}_{i=1}^{n_j} \), such that the classical solutions \( \hat{\varphi}_\varepsilon = (\hat{\varphi}_{j,i})_{i=1}^{n_j} \) to the system of equations

\[
(\partial_t - \Delta)\hat{\varphi}_{j,i} = F_j(\hat{\varphi}_\varepsilon, \nabla \hat{\varphi}_\varepsilon) - \sum_{i=1}^{n_j} c_{j,i}(\varepsilon) P_{j,i}(\hat{\varphi}_\varepsilon, \nabla \hat{\varphi}_\varepsilon) + \varepsilon^{(e)}_j, \quad (1.3)
\]

converge in probability as \( \varepsilon \downarrow 0 \) to a tuple \( \varphi \) of limiting random distributions, which can be viewed as “a solution” to the system of equations \([1.1]\) and which does not depend on the specific choice of approximation \( \varepsilon^{(e)}_j \). This process of using approximations where one regularises at a certain scale and then modifies the non-linearity in a way that depends on this regularisation scale is called renormalisation.

**Remark 1.1** One may worry about the fact that \([1.3]\) no longer seems to relate to the “real” equation \([1.1]\) due to the presence of the additional counterterms \( P_{j,i}(\cdot, \cdot) \). From a physical perspective however, this is not as unnatural as it may seem. Indeed, what one can typically “guess” from physical arguments is not the specific system of equations \([1.1]\), but rather the generic form of such a system, with the nonlinearities \( F_j \) involving a priori unknown parameters (‘coupling constants’) that then need to be determined a posteriori by matching predictions with experiments. From this perspective, \([1.3]\) is actually also of the form \([1.1]\) and simply corresponds to an \( \varepsilon \)-dependent reparametrisation of the family of equations under consideration. One way of interpreting this is that the whole family of solutions given by \([1.1]\) and indexed by a suitable finite-dimensional collection of possible nonlinearities \( F \) converges to a limiting family of solutions as \( \varepsilon \to 0 \), but the collection of nonlinearities has to be suitably reparametrised in the process. A trivial but analogous situation is the following. For any fixed \( \varepsilon \), consider the subset \( A_\varepsilon \subset \mathbb{R}^2 \) parametrised by \( \mathbb{R} \) and given by \( A_\varepsilon = \{ (x_\varepsilon(t), y_\varepsilon(t)) : t \in \mathbb{R} \} \), where

\[
x_\varepsilon(t) = \varepsilon t + \frac{2}{\varepsilon}, \quad y_\varepsilon(t) = \varepsilon \cos(t). \]

While it is clear that \( A_\varepsilon \to A_0 \) with \( A_0 = \mathbb{R} \times \{ 0 \} \), \( x_\varepsilon \) and \( y_\varepsilon \) do not converge to a parametrisation of \( A_0 \), although they do if we perform the \( \varepsilon \)-dependent reparametrisation \( t \mapsto t/\varepsilon - 2/\varepsilon^2 \) and write instead \( A_\varepsilon = \{ (\hat{x}_\varepsilon(t), \hat{y}_\varepsilon(t)) : t \in \mathbb{R} \} \) with

\[
\hat{x}_\varepsilon(t) = t, \quad \hat{y}_\varepsilon(t) = \varepsilon \cos\left(\frac{t}{\varepsilon} - \frac{2}{\varepsilon^2}\right). \]

In this analogy, \( t \) plays the role of \( F \), \( (x_\varepsilon, y_\varepsilon) \) plays the role of the solution map \( \varphi_\varepsilon \), while \( (\hat{x}_\varepsilon, \hat{y}_\varepsilon) \) plays the role of the “renormalised” solution map \( \hat{\varphi}_\varepsilon \). While perturbative methods can shed light on the mechanics of renormalisation, they are limited to proving statements about the term by term behaviour of formal expansions for \( \hat{\varphi}_\varepsilon \) which one does not expect to be summable. The jump from knowing how to set up approximations such as \([1.3]\) to showing that the solutions \( \hat{\varphi}_\varepsilon \) do actually converge as \( \varepsilon \downarrow 0 \) requires fundamentally new ideas and is the main achievement of the methods developed in \([\text{Hai}14], [\text{GIP}15], [\text{Kup}16], [\text{OW}16]\).
## 1.1 A review of the theory of regularity structures

The setting of the current work is the theory of regularity structures [Hai14], so we quickly present the theory’s central ideas. Those seeking more pedagogical expositions are encouraged to look at [FH14, CW15, Hai16b]. The approach of the theory can be illustrated by the diagram shown in Figure 1.

In this figure, $\text{Eq}$ denotes a space of possible equations. While the instances of $\text{Eq}$ on the top and bottom lines can be thought of as the same, we will see them as playing different roles. The choice of an element in $\text{Eq}$ on the bottom line will be called a concrete equation and the choice of an element in $\text{Eq}$ on the top line will be called an abstract equation.

Continuing on the bottom line, we denote by $\mathcal{C}$ a space of continuous (or sufficiently smooth) functions defined on the underlying space-time – this is where regularised realisations of our driving noise live, but this space is typically much too small to contain instances of the limiting noise $\xi$. The space $\mathcal{C}^\alpha$ is a Hölder-type space of space-time functions / distributions where the solution to the equation at hand will live. Given a concrete equation and a regularised driving noise $\xi^{(\epsilon)}$ the classical solution map $S_C$ returns the solution to the specified concrete equation starting from $0$ (or some other specified initial condition) and driven by $\xi^{(\epsilon)}$.

While the map $S_C$ is well-defined when the driving noise is drawn from $\mathcal{C}$, it lacks sufficient continuity in this argument to be well-defined on any of the distributional spaces in which the convergence $\xi = \lim_{\epsilon \downarrow 0} \xi^{(\epsilon)}$ takes place. This is actually already the case for stochastic ordinary differential equations, see [Ly091].

The theory of regularity structures follows the philosophy of (controlled) rough paths [Ly098, Gub04, LCL07, FV10, FH14] and builds a continuous solution map $S_A$ at the price of defining it on a richer space – one must feed into the map $S_A$ not just a realisation of the driving noise but also a suitable “enhancement”, which encodes various multilinear functionals of the driving noise that are a priori ill-defined.
Such a collection of data is referred to as a model in the terminology of regularity structures, with the space of models \( \mathcal{M} \) being a fairly complicated non-linear metric space. The multilinear functionals one must define in order to specify an element of \( \mathcal{M} \) are such that they can be defined canonically when evaluated on regularised instances of the noise but have no such interpretation when evaluated on an un-regularised realisation – this is because one encounters ill-defined pointwise products of rough functions and distributions. Consequently, on the space of regularised realisations of the noise \( \mathcal{C} \), one has a canonical lift \( \Psi : \mathcal{C} \to \mathcal{M} \) but this lift does not extend continuously to typical realisations of \( \xi \).

One can also define a bundle \( D^\gamma \) of Hölder-type spaces of abstract jets over \( \mathcal{M} \) where the abstract equation can be formulated as a well-posed fixed point problem. The fixed point yields a solution map \( S_A \) that is a continuous section of the bundle \( D^\gamma \): given \( Z \in \mathcal{M}, S_A[Z] \) belongs to the fibre over the model \( Z \).

The map \( R \) appearing on the very right is the reconstruction operator which is a continuous map from the bundle \( D^\gamma \) to some Hölder space \( C^\alpha \) of space-time functions / distributions. The key point of the diagram above is that the square commutes, namely \( R \circ S_A \circ \Psi = S_C \). This factorisation of \( S_C \) separates difficulties: the map \( \Psi \) is discontinuous, but has the advantage of being given explicitly, while the map \( S_A \) is given as the solution to a fixed point problem but has the advantage of being continuous.

The incorporation of renormalisation in the abstract setting is done by replacing the canonical lift \( \Psi : \mathcal{C} \to \mathcal{M} \) by a different lift which is allowed to break the usual definition of a product. The space of those deformations of the product that are allowed and that preserve stationarity is itself rather small. In particular, one can exhibit a finite-dimensional Lie group \( \mathcal{R} \) acting on \( \mathcal{M} \) (in this case by a right action or equivalently by a left action of the adjoint) which parametrises all “natural” lifts of the noise. The art of renormalisation then involves remembering that \( \xi^{(\varepsilon)} \) is random, and choosing, for each \( \varepsilon > 0 \), a deterministic element \( M_\varepsilon \in \mathcal{R} \), determined by the law of \( \xi^{(\varepsilon)} \), such that the random models \( M_\varepsilon \circ \Psi[\xi^{(\varepsilon)}] \) converge in probability as \( \varepsilon \to 0 \). If this can be done, then thanks to the pathwise continuity of \( R \) and \( S_A \), one concludes that

\[
\hat{S}_C[\xi^{(\varepsilon)}] \overset{\text{def}}{=} R \circ S_A \circ M_\varepsilon \circ \Psi[\xi^{(\varepsilon)}] \tag{1.4}
\]

also converges in probability as \( \varepsilon \to 0 \) to some limiting "renormalised solution map" \( \hat{S}_C \), which is only defined almost surely with respect to the law of \( \xi \).

The overall framework of the theory of regularity structures was set forth in [Hai14]. The theory was designed to be robust and fairly automated in that it does not need to be modified on an equation by equation basis but three of the above steps were left to the person applying the theory in general:

---

2 Strictly speaking, the space \( D^\gamma \) doesn’t satisfy the axioms of a vector bundle because fibres corresponding to different models are not isomorphic in general. At an algebraic level, the object in each fibre is always a “jet”-valued function, but the analytic requirements we impose on this do depend on the underlying model and can be very different, even for nearby fibres.
(i) the construction of a Lie group $\mathcal{R}$ rich enough to contain $\{M_\varepsilon\}_{\varepsilon > 0}$.
(ii) proving the convergence of the renormalised models $M_\varepsilon \circ \Psi[\xi^{(\varepsilon)}]$,
(iii) showing that $S_C^{(\varepsilon)}$ actually coincides with the classical (not renormalised) solution map, but for a modified equation.

Robust theorems which automate the first two of these steps were recently obtained in [BHZ16] and [CH16], respectively. The aim of the current article is to give a general proof of the last step.

Note that the action of $M_\varepsilon$ on the top line of Figure 1 doesn’t change the fixed point problem used to build the map $S_A$, it only changes the model which is used as an input to this map. This deformation of the canonical lift generates a discrepancy between how we interpret products on the top and bottom lines of our diagram and as a result $\hat{S}_C^{(\varepsilon)} \neq S_C$. The purpose of the present article is to describe a corresponding action of $\mathcal{R}$ on a suitable space of equations $\text{Eq}$ so that the identity

$$(\mathcal{R} \circ S_A)(F, M^* \Psi(\xi)) = S_C(MF, \xi),$$

holds for every smooth noise $\xi$, every right hand side $F \in \text{Eq}$, and every $M \in \mathcal{R}$.

In [BCFP17], the authors identified such an action in the simpler setting of regularity structures arising from branched rough paths, which gave rise to a natural morphism of pre-Lie algebras. The approach in [BCFP17] inspired that of the present work, however the setting here is quite a bit more complex.

The problem of identifying the action of the renormalisation group on the equation is also found in perturbative quantum field theory (QFT) where one checks that the counterterms one would like to insert in order to make individual Feynman diagrams finite can be generated order by order by changing the coupling constants in the Lagrangian that was used to generate these terms in the first place. The fact that the Lagrangian can be modified in this way can usually be checked quite easily on a case by case basis—examples can be found in any textbook on QFT. However, we have not been able to find work analogous to the present work in the perturbative QFT literature—this would be a theorem which gives an explicit and model-independent formalism for deriving renormalised Lagrangians.

**Remark 1.2** Continuing the thread of Remark 1.1, we can view our full space of equations as being parameterised by a family of coupling constants $\vec{c} = (c_{j,i}) \in \mathbb{R}^K$, where we range across $1 \leq j \leq m$, $1 \leq i \leq n_j$, and $K = \sum_{j=1}^m n_j$. The correspondence between the coupling constants $\vec{c}$ and the equation is given by (1.3). The dual action of the renormalisation group on the equation is then just a representation of $\mathfrak{R}$ on $\mathbb{R}^K$.

As shown in [CH16], we can choose the sequence $M_\varepsilon$ to depend on our choice of sequence $\varrho_\varepsilon$ of approximate identities in such a way that the limit $M_\varepsilon[\varrho_\varepsilon]^* \circ \Psi[\xi \ast \varrho_\varepsilon]$ is independent of the choice of $\varrho_\varepsilon$. Once one has obtained one limiting model $\lim_{\varepsilon \downarrow 0} M_\varepsilon^* \Psi[\xi^{(\varepsilon)}]$, then an entire family of models is obtained via

$$\left\{ \lim_{\varepsilon \downarrow 0} M_\varepsilon^* \Psi[\xi^{(\varepsilon)}] : M \in \mathcal{R} \right\}.$$

(1.5)
Once one fixes an initial choice \( \vec{c} \) of coupling constants, every model in (1.5) gives rise to a notion of solution which can be obtained as the \( \varepsilon \downarrow 0 \) limit of the classical solution to (1.4) driven by \( \xi^{(e)} \) and with coupling constants given by \( MM_{\varepsilon} \vec{c} \).

We stress that there is in general not a canonical model or solution theory that can be pointed out in the family (1.5). This is because, even though the BPHZ lift constructed in [BHZ, CH] seems canonical to a certain extent, it depends in general on an arbitrary choice of (scale 1) cutoff in the Green’s function for the linear system. Different choices of cutoff yield solutions that differ by the action of an element of \( \mathfrak{R} \), but no single choice of cutoff is more canonical than the others in general. We reiterate that

(i) If a specific solution is required for modelling purposes, then its parameters do have to be determined by comparisons with data/experiments anyway. This will then determine a unique element of the family of solutions, which is independent of the parametrisation of the family that is being used.

(ii) The exact same sensitivity/indeterminacy in the notion of solution is present already in the case of the theory of integration against Brownian motion.

1.2 Outline of the paper

Section 2 introduces the bare minimum in order to state an existence result, namely Theorem [2.13] which is applicable to a wide class of semilinear SPDEs. This section can be read without any prior knowledge of the theory of regularity structures and, with the exception of Section 2.1, it can be skipped by those who are more interested in learning the method of proof for the main results of this paper. In Section 2.8 we illustrate two applications of Theorem [2.13] to the generalised KPZ equation and the dynamical \( \Phi_{4-\delta} \) model for any \( \delta > 0 \).

In the early parts of Section 3 we recall some of the basic algebraic definitions from the theory of regularity structures and describe how we specialize them for our purposes. In Section 3.4 we introduce a formalism that allows us to efficiently deal with some of the combinatorial symmetry factors that appear when we work with spaces of combinatorial decorated trees.

After this preliminary work, we introduce the notion of coherence in Section 3.7 which plays a central role in the paper. Given a PDE determined by some right hand side \( F \), we first define a function \( \Upsilon^F[\cdot] \) on the trees of the corresponding regularity structure. In the case of a single scalar equation, we then say that a linear combination of trees \( U \) is coherent if the coefficient of every tree of the form \( I[\tau] \) in the expansion of \( U \) is given by \( \Upsilon^F[\tau] \) evaluated on the coefficients of the

---

3This is not just an analogy as integration against Brownian motion falls within the framework of regularity structures and the choice between Itô and Stratonovich integrals, or some interpolation of the two, is parameterised by the corresponding renormalisation group. The difference is that, in the case of SDEs, no renormalisation is in principle required and every smooth regularisation of Brownian motion yields the Stratonovich solution in the limit. On the other hand, the BPHZ renormalisation procedure, which is the natural way of centring random models used in the present article, always yields the Itô solution in the limit. (In the special case of SDEs, the effect of the cutoff of the Green’s function happens to vanish in the limit.)
polynomial part of $U$. After introducing this concept, we present the first of two key lemmas, Lemma 3.16 which states that coherence of $U$ with $F$ is equivalent to $U$ satisfying a fixed point problem determined by $F$.

In Section 3.8 we describe how $\Upsilon^*$ allows us to define an action of the renormalization group $\mathcal{R}$ on the space of $F$’s which we write $F \mapsto MF$ for $M \in \mathcal{R}$. We can then present our second key lemma, Lemma 3.18, which states that any renormalisation operator $M \in \mathcal{R}$ takes expansions coherent with respect to $F$ to expansions coherent with respect to a new nonlinearity $MF$. We conclude Section 3 by presenting the main theorem of this paper, Theorem 3.20, which gives the general form of the action of the renormalisation group onto a suitable space of nonlinearities, and show how this theorem follows from Lemmas 3.16 and 3.18.

Sections 4 and 5 are devoted to developing an algebraic/combinatorial framework in which we can prove Lemmas 3.16 and 3.18. In Section 4 we introduce a new collection of trees which carry more data through additional decorations which greatly facilitates the proof of Lemma 3.16. In Section 5 we define various “grafting” operations on trees. A key result here is Proposition 5.14 which states that a certain space of trees is the “universal free object” corresponding to our grafting operators. We then also state lemmas showing that the maps $\Upsilon^*$ and the renormalisation operators $M \in \mathcal{R}$ all have “morphism” properties with respect to these grafting operators. This, when combined with Proposition 5.14, allows us to prove Lemma 3.18.

Section 6 is the analytic part of our paper which is needed to prove Theorem 2.13. Sections 6.1, 6.2 and 6.3 recall many analytic objects in the theory of regularity structures and describe how we will specialize them for our purposes. In Section 6.4 we state and prove Theorem 6.7 which is obtained by combining Theorem 3.20 with the analytic theory given in the earlier parts of Section 6. One novel aspect of Theorem 2.13 is that it states, with full generality, to what degree one can expect to “restart” solutions to the class of SPDE under consideration and consequently what a natural notion of “maximal solution” should be. To facilitate this, we develop a new argument which could be loosely described as an analogue of the Da Prato–Debussche trick [DPD03] in the space of modelled distributions – this is the content of Section 6.5.

In Appendix A.1 we state a technical result describing how the renormalisation of nonlinearities influences the trees they generate via Duhamel expansion. In Appendix A.2 we give a multivariate Faa Di Bruno formula which allows us to show that work performed on the “richer” space of trees introduced in Section 4 collapses appropriately to the smaller trees which populate the regularity structure. In Appendix A.3 we give the details of the proofs describing how renormalisation interacts with the grafting operations, which leverages the co-interaction property of [BHZ16]. In Appendix A.4 we describe how the techniques of [CL01] can be used to prove Proposition 5.14. In Appendix A.5 we describe how our abstract result can be combined with the framework of regularity structures to prove Theorem 2.13.

The reader need not have any familiarity with [CH16], but some familiarity with the frameworks of [Hai14] and [BHZ16] is assumed throughout the paper.
2 A black box theorem for local well-posedness of SPDEs

2.1 Preliminary notation

Throughout this article, we adopt the standard conventions $\sup \emptyset \overset{\text{def}}{=} -\infty$ and $\inf \emptyset \overset{\text{def}}{=} +\infty$. We freely use multi-index notation. For any set $A$, $a \in A$, and $\theta \in \mathbb{N}^A$ we usually write $\theta[a]$ for the $a$-component of $\theta$, $|\theta| \overset{\text{def}}{=} \sum_{a \in A} \theta[a]$, and $\theta! \overset{\text{def}}{=} \prod_{a \in A} \theta[a]!$. For a vector of commuting indeterminates (or real numbers) $x = (x_a)_{a \in A}$, we similarly write $x^\theta = \prod_{a \in A} (x_a)^{\theta[a]}$. For any $a \in A$ we define $e_a \in \mathbb{N}^A$ by setting $e_a[b] \overset{\text{def}}{=} 1\{a = b\}$ for $b \in A$.

In [BHZ16] and in this paper one often uses the notion of multisubsets of some fixed set $A$. By saying $B$ is a multisubset of $A$ we are indicating that $B$ can contain certain elements of $A$ with multiplicity. In [BHZ16] the collection of all multisubsets of $A$, denoted by $\mathcal{P}(A)$, is given by $\bigcup_{n \geq 0}[A]^n$ where $[A]^n$ is $A^n$ quotiented by permutation of entries. We will implicitly identify $\mathcal{P}(A)$ with $\mathbb{N}^A$.

In particular, for $b \in \mathbb{N}^A$ we adopt the notational convention that

$$\sum_{a \in b} x_a \overset{\text{def}}{=} \sum_{a \in A} b[a] x_a. $$

Similarly, for $b_1, b_2 \in \mathbb{N}^A$, writing the interpretation as “multi-sets” like in [BHZ16] on the left and multi-indices on the right, one has

$$b_1 \cap b_2 = \min\{b_1, b_2\}, \quad b_1 \cup b_2 = \max\{b_1, b_2\},$$

$$b_1 \sqcup b_2 = b_1 + b_2, \quad b_1 \preceq b_2 \iff b_1 \leq b_2. $$

We fix for the rest of the paper a dimension of space $d \geq 0$. We define our space-time to be $\Lambda \overset{\text{def}}{=} \mathbb{R} \times T^d$ with the first component being referred to as “time”. We write $\{\partial_t\}_{t=0}^d$ for the corresponding partial derivatives with respect to space-time. We will also sometimes identify functions on $\Lambda$ with functions on $\mathbb{R}^{d+1}$ by periodic continuation. A space-time scaling $\varsigma$ is a tuple $\varsigma = (\varsigma_i)_{i=0}^d \in [1, \infty)^{d+1}$ with non-vanishing components. Given a space-time scaling $\varsigma$ we set $|\varsigma| \overset{\text{def}}{=} \sum_{i=0}^d \varsigma_i$, and, for any $\varepsilon > 0$, we define a scale transformation $S^{\varepsilon}_{\varsigma}$ on functions $\varrho: \mathbb{R}^{d+1} \to \mathbb{R}$ by setting $(S^{\varepsilon}_{\varsigma}\varrho)(z_0, \ldots, z_d) \overset{\text{def}}{=} \varepsilon^{-|\varsigma|} \varrho(\varepsilon^{-\varsigma_0} z_0, \ldots, \varepsilon^{-\varsigma_d} z_d)$.

We also introduce a notion of $\varsigma$-degree $|k|_{\varsigma}$ of a multi-index $k \in \mathbb{N}^{d+1}$ by setting $|k|_{\varsigma} = \sum_{i=0}^d k[i] \varsigma_i$. This gives a corresponding notion of $\varsigma$-degree for polynomials.

---

*The case $d = 0$ corresponds to working with stochastic differential equations.*
and $s$-degree of partial derivatives. We define a scaled distance $| \cdot | s$ on $\Lambda$ as usual by setting $| z | s \defeq \sum_{i=0}^{d} | z_i |^{1/s_i}$. We often write $\tilde{s} = (s_i)_{i=1}^{d}$ for the associated space-scaling on $\mathbb{R}^d$. Clearly, one has natural analogues of all the above notation when working with distances and degrees of polynomials/derivatives on $\mathbb{R}^d$ with respect to the scaling $\tilde{s}$ and we use these in what follows.

### 2.2 Hölder-Besov Spaces

While the bulk of this paper is algebraic/combinatorial, our statement and proof of the main theorem of Section 2.7 requires us to reference scaled Hölder-Besov spaces. This subsection can be skipped by those readers who are more interested in our main result Theorem 6.7 as opposed to Theorem 2.13.

We first specialize to the case of $\alpha \in (0, \infty) \setminus \mathbb{N}$. We define, for every compact set $\mathfrak{K} \subset \Lambda$ and any function $f : \mathfrak{K} \to \mathbb{R}$,

$$
\| f \|_{\alpha, \mathfrak{K}} \defeq \sup_{\tilde{z} \in \mathfrak{K}} \inf \left\{ \sup_{z \in \mathfrak{K}, |z - \tilde{z}|_s \leq 1} \frac{|(\partial^{k} f)(\tilde{z}) - (\partial^{k} P)(\tilde{z} - z)|}{|z - \tilde{z}|^{|\alpha| - |k|_s}} : \deg_s P \leq |\alpha| \right\},
$$

where $\deg_s P$ denotes the $s$-degree of the polynomial $P$. We then define $C^{\alpha}_s(\Lambda)$ to be the collection of $f : \Lambda \to \mathbb{R}$ with $\| f \|_{\alpha, \mathfrak{K}} < \infty$ for every compact $\mathfrak{K} \subset \Lambda$, and we equip it with a metric induced by these seminorms. If $d = 1$ and $s = 1$ then $C^{\alpha}_s(\Lambda)$ just corresponds to functions that admit $|\alpha|$ continuous derivatives and whose $|\alpha|$-th derivative is Hölder continuous of index $\alpha - |\alpha|$.

We now define $C^{\alpha}_s(\Lambda)$ for $\alpha \in (-\infty, 0)$. First, for every $r \in \mathbb{N}$ and $z \in \Lambda$ we define $B_{z,r}$ to be the collection of all smooth functions $\omega : \Lambda \to \mathbb{R}$ which are supported on the ball $\{ \tilde{z} \in \Lambda : |\tilde{z} - z|_s \leq 1 \}$ and satisfy $\sup_{\tilde{z} \in \Lambda} |D^{k}\omega(\tilde{z})| \leq 1$ for every $k \in \mathbb{N}^d$ with $|k|_s \leq r$. For any compact $\mathfrak{K} \subset \Lambda$ and distribution $f \in \mathcal{D}'(\Lambda)$, we then set

$$
\| f \|_{\alpha, \mathfrak{K}} \defeq \sup \left\{ \lambda^{-|\alpha|} |(f, S^{\lambda}_\alpha \omega)| : z \in \mathfrak{K}, \omega \in B_{z,-|\alpha|}, \lambda \in (0, 1) \right\}.
$$

and we define $C^{\alpha}_s(\Lambda)$ to be the collection of distributions $f$ with $\| f \|_{\alpha, \mathfrak{K}} < \infty$ for every compact $\mathfrak{K} \subset \Lambda$. As before, we equip $C^{\alpha}_s(\Lambda)$ with a metric induced by these seminorms. The spaces $C^{\alpha}_s(\mathbb{T}^d)$, $\alpha \in \mathbb{R}$, are defined in the analogous way.

### 2.3 Types, non-linearities, and functional derivatives

We fix a finite set $\mathcal{L}_-$ which will index the set of rough driving noises that appear in our system of SPDEs and a finite set $\mathcal{L}_+$ which will index the set of components of our system of SPDEs. We also fix a degree assignment $| \cdot |_s$ on $\mathcal{L}_- \sqcup \mathcal{L}_+$ with $\mathcal{L}_- \sqcup \mathcal{L}_+$ which takes strictly negative values on $\mathcal{L}_-$ and strictly positive ones on $\mathcal{L}_+$. For any multi-set $A$ of elements of $\mathcal{L}$ we define $|A|_s \defeq \sum_{i \in A} |t|_s$.

We define an indexing set $\emptyset \defeq \mathcal{L}_+ \times \mathbb{N}^{d+1}$ and write elements of this set as $(b, q) \in \emptyset$ with $b \in \mathcal{L}_+$ and $q \in \mathbb{N}^{d+1}$. For $(b, q) \in \emptyset$ we write $| (b, q) |_s \defeq |b|_s - |q|_s$, where $|q|_s = \sum_{i=0}^{d} q_i s_i$. One should think of $\emptyset$ as indexing all the solutions and
derivatives of solutions of our system of SPDEs. We also assume that we have a partition \( \emptyset \overset{\text{def}}{=} \emptyset_+ \sqcup \emptyset_- \). This partition corresponds to an a priori assumption that the elements of \( \emptyset_- \) will index space-time distributions of negative regularity, while \( \emptyset_+ \) will index functions of positive regularity, see Section 2.5. We introduce a family of commuting indeterminates \( \mathcal{X} \overset{\text{def}}{=} (\mathcal{X}_o)_{o \in \emptyset} \). The indeterminate \( \mathcal{X}_o \) will, depending on context, serve as a placeholder for a portion of the abstract expansion corresponding to the (derivative of the) component of the solution indexed by \( o \) or for a reconstruction of that expansion.

We write \( \mathcal{C}_\emptyset \) for the real algebra of smooth functions on \( \mathbb{R}^\emptyset \) which depend on only finitely many components, which we henceforth identify with functions of \( \mathcal{X} \). Given \( F \in \mathcal{C}_\emptyset \) we write \( \emptyset(F) \) for the minimal subset of \( \emptyset \) such that \( F \) does not depend on any components of \( \emptyset \) outside of \( \emptyset(F) \).

We introduce two types of differential operators on \( \mathcal{C}_\emptyset \). For \( o \in \emptyset \) we write \( D_o : \mathcal{C}_\emptyset \to \mathcal{C}_\emptyset \) for the operation of differentiation with respect to \( \mathcal{X}_o \). We also define, for every \( 0 \leq i \leq d \), and every \( (t,p) \in \emptyset \), \( \partial_i \mathcal{X}_{(t,p)} = \mathcal{X}_{(t,p+e_i)} \) and we impose the chain rule:

\[
\partial_i F \overset{\text{def}}{=} \sum_{o \in \emptyset} \partial_i \mathcal{X}_o D_o F.
\]

We define \( \mathcal{D} \) to be the sub-algebra of \( \mathcal{C}_\emptyset \) consisting of all elements \( F \in \mathcal{C}_\emptyset \) for which there exists \( \alpha \in \mathbb{N}^\emptyset \) supported on \( \emptyset_- \) with \( D^\alpha F = 0 \).

Observe that every \( F \in \mathcal{D} \) admits a unique (modulo permutations of the index \( j \)) expansion

\[
F(\mathcal{X}) = \sum_{j=1}^{m} F_j(\mathcal{X}) \mathcal{X}^{\alpha_j},
\]

where (i) \( \alpha_1, \ldots, \alpha_m \in \mathbb{N}^\emptyset \) are distinct, supported on \( \emptyset_- \), and have only finitely many non-zero components and (ii) for all \( 1 \leq j \leq m \), the element \( F_j(\mathcal{X}) \) is not identically 0 and \( \emptyset(F_j) \subset \emptyset_+ \).

**Lemma 2.1** Let \( F \in \mathcal{C}_\emptyset \) and \( k \in \mathbb{N}^{d+1} \setminus \{0\} \). Then \( \partial^k F = 0 \) if and only if \( F \) is constant.

**Proof.** If \( F \) is constant, then evidently \( \partial^k F = 0 \). Conversely, suppose \( F \) is not constant. Then there exists a (not necessarily unique) element \( (t,p) \in \emptyset \) for which \( D_{(t,p)} F \neq 0 \) but \( D_{(\bar{t},\bar{p})} F = 0 \) for all \( \bar{p} > p \). Using Definition 2.2 the fact that \( D_o \) and \( D_{\bar{o}} \) commute, and that \( D_o \mathcal{X}_o = \delta_{o,\bar{o}} \), we see that \( D_{(t,p+e_i)} \partial_i F = D_{(t,p)} F \) for every \( i \in \{0, \ldots, d\} \), whence we conclude that \( \partial_i F \) is not constant either. The conclusion then readily follows by induction. \( \square \)

### 2.4 Example: the generalised KPZ equation

We make a small aside to clarify the abstract notation we have introduced above by looking at how a concrete example can be recast in this setting. Some of the particular choices we make here are motivated in Section 2.8.1

---

*See (A.2).*
We consider the generalised KPZ equation (as described in [Hai16a]), a natural stochastic evolution on loop space. We set $d = 1$, $s = (2, 1)$, fix $n > m \geq 1$, $\mathcal{L}_+ = \{1, \ldots, m\}$, and $\mathcal{L}_- = \{1, \ldots, n\}$ (since $\mathcal{L}_+$ always indexes kernels and $\mathcal{L}_-$ always indexes noises, which is which will be clear from context). Working in local coordinates on a manifold of dimension $m$, we are looking for the solution $(u_i)_{i=1}^n$ to the system of equations given by

$$\partial_t u_i = (\partial_x^2 - 1)u_i + u_i + \sum_{j,k=1}^m \Gamma^i_{j,k}(u)(\partial_x u_j)(\partial_x u_k) + \sum_{r=1}^n \sigma^i_r(u)\xi_r, \quad 1 \leq i \leq m,$$

where we write $(t, x)$ rather than $(z_0, z_1)$ for the space-time coordinates. Here the $\{\xi_r\}_{r=1}^n$ are independent space-time white noises, the $(\Gamma^i_{j,k})$ are the Christoffel symbols of the underlying manifold. The $\sigma_r$ are a collection of smooth vector fields on the manifold generating its metric in the sense that $\sum_{r=1}^n L_{\sigma_r}^2 = \Delta$, the Laplace-Beltrami operator, where $L_{\sigma}$ is the Lie derivative in the direction of $\sigma$. Note that these vector fields and Christoffel symbols only depend on $u$ itself, not on its derivatives. Recasting this in our earlier notation, we set $|l|_s \overset{\text{def}}{=} 2$ for every $t \in \mathcal{L}_+$, which encodes the fact that the Green’s function of $(\partial_x^2 - 1)$ increases the regularity of the solution by two degrees of differentiability in the parabolic scaling. We also fix some $\kappa \in (0, \frac{1}{2})$ and, for every $\ell \in \mathcal{L}_-$, we set $|\ell|_s = -\frac{3}{2} - \kappa$. This encodes the path-wise parabolic regularity estimate on the driving space-time noises $\{\xi_r\}_{r=1}^n$ which guarantees that each $\xi_r$ belongs almost surely to $C_{\frac{3}{2}+\kappa}$.

We then have $\mathcal{O}_+ = \{(i, 0)\}_{i=1}^m$ and the non-linearity $F = (F^l_i : t \in \mathcal{L}_+, \ell \in \mathcal{L}_- \cup \{0\})$ is given by setting, for $1 \leq i \leq m$,

$$F^l_i \overset{\text{def}}{=} \begin{cases} \mathcal{X}_{(i, 0)} + \sum_{j,k=1}^m \Gamma^i_{j,k}(\mathcal{X})\mathcal{X}_{(j, (0, 1))}\mathcal{X}_{(k, (0, 1))} & \text{if } \ell = 0, \\ \sigma^i_r(\mathcal{X}) & \text{otherwise.} \end{cases}$$

### 2.5 Regularity pairs and subcriticality

Given any function $f$ from $\mathcal{L}$ (resp. $\mathcal{L}_+$) to $\mathbb{R}$, we extend $f$ canonically to $\mathcal{L} \times \mathbb{N}^{d+1}$ (resp. $\mathcal{L}_+ \times \mathbb{N}^{d+1}$) by setting $f(t, p) \overset{\text{def}}{=} f(t) - \lvert p \rvert_s$. Fix then a map $\text{reg} : \mathcal{L} \to \mathbb{R}$ for which the following hold.

1. One has $o \in \mathcal{O}_+$ if and only if $(\pm) \text{reg}(o) > 0$.
2. For every $\ell \in \mathcal{L}_-$ one has $\text{reg}(\ell) < |\ell|_s$. (Recall that $|\ell|_s < 0$ in this case.)

For $t \in \mathcal{L}_+$ one should think of the quantity $\text{reg}(t)$ as an estimate of the space-time regularity of the distribution / function associated to $t$. For $\ell \in \mathcal{L}_-$ the quantity $\text{reg}(\ell)$ can be taken arbitrarily close to but strictly smaller than $|\ell|_s$ — this doesn’t really encode any new information, but such a convention will be convenient later on to gain a little bit of “wriggle room”.

**Definition 2.2** Suppose we are given a tuple $F = (F^l_i)_{t, \ell}$, where $t$ ranges over $\mathcal{L}_+$, $\ell$ ranges over $\mathcal{L}_- \cup \{0\}$, and for each $t, \ell$ one has $F^l_i \in \mathcal{P}$. We say $F$ obeys $\text{reg}$ if the following condition holds.
For every \( t \in \mathcal{L}_+ \) and \( l \in \mathcal{L}_- \), if one expands \( F^l_t \) as in (2.7) then for every exponent \( \alpha \in \mathbb{N}^d \) appearing in the expansion of \( F^l_t \) one has
\[
\text{reg}(t) < |t|_s + \text{reg}(l) + \sum_{o \in \alpha} \text{reg}(o).
\]
We define \( \mathfrak{G} \) to be the set of all tuples \( F \) which obey reg.

Condition (2.4) enforces that the assumptions on regularity encoded by reg are self-consistent when checked on an equation with right hand side determined by \( F \), namely the system of SPDEs formally given by
\[
\partial_t u_t = \mathcal{L}_t u_t + F^l_t(u, \partial_t u, \ldots) + \sum_{i \in \mathcal{L}_-} F^i(t, u, \partial_t u, \ldots) \xi_t.
\]
They also guarantee that the SPDE associated to \( F \) can be algebraically formulated using a regularity structure built in [BHZ10]. If there exists a function reg such that \( F \) obeys reg, then \( F \) is said to be \textit{locally subcritical}.

To guarantee the existence of local solutions however, extra assumptions are needed. Fix a function \( \text{ireg} : \mathcal{L}_+ \to \mathbb{R} \). One should think of \( \text{ireg}(t) \) as the space regularity of the initial condition for the “remainder” part of the \( t \) component of our SPDE (see Section 2.7).

For \( t \in \mathcal{L}_+ \) and \( F^l_t \) as in (2.3) with multisets \( \alpha^l_j \) for \( j \leq m_l \) where \( m_l \) is the corresponding value of \( m \) in (2.3), define
\[
n_t \defeq \min_{l \in \mathcal{L}_- \cup \{0\}} \left\{ |l|_s + \min_{1 \leq j \leq m_l} \min_f \sum_{o \in \alpha^l_j} f_o(o) \right\},
\]
where \( \min_f \) is taken over all assignments \( f : o \mapsto f_o \in \{ \text{reg}, \text{ireg} \} \) which, for those \( j \) such that \( (F^l_t)_j \) is identically constant, satisfy \( f^{-1}(\text{ireg}) \cap \alpha^l_j \neq \emptyset \).

Remark 2.3 If \( F^l_t \) itself is identically constant for some \( l \in \mathcal{L}_- \cup \{0\} \), then \( m_l = 1 \) and \( \alpha^l_1 = 0 \), so that \( \min_f \) is taken over the empty set. Due to our convention \( \inf \emptyset \defeq +\infty \), the value in the parentheses \( \ldots \) in (2.6) is then \( +\infty \) for this \( l \).

Assumption 2.4 For every \( o \in \mathcal{O}_+ \), it holds that \( 0 \leq \text{ireg}(o) \leq \text{reg}(o) \). Moreover, for every \( t \in \mathcal{L}_+ \), it holds that \( n_t > -\delta_0 \) and \( n_t + |t|_s > \text{ireg}(t) \).

The first condition of Assumption 2.4 is required to deal with the composition of solutions with smooth functions, while the second condition is required to reconstruct products of singular modelled distributions which appear in the abstract fixed point map associated to our equation.

Remark 2.5 In practice one starts with a specific system of equations, then fixes a scaling \( s \), computes the regularisation of the kernels \( \{|l|_s\}_{l \in \mathcal{L}_+} \) and regularity of the noises \( \{|l|_s\}_{l \in \mathcal{L}_-} \), encodes the non-linearities that appear in terms of a rule, and then tries to determine the functions reg and ireg. We introduce notions in a different order because, from the outset, we always want to consider a whole family of equations on which the renormalisation group will then be able to act.
2.6 Kernels on the torus

We make the following standing assumption regarding the linear part of our equation.

**Assumption 2.6** For each \( t \in \Sigma^+ \), we are given a differential operator \( \mathcal{L}_t \) involving only the spatial derivatives \( \{ \partial_i \}_{i=1}^d \) which satisfies the following properties.

- \( \partial_0 - \mathcal{L}_t \) admits a Green’s function \( G_t : \Lambda \setminus \{0\} \to \mathbb{R} \) which is a kernel of order \( |t|_s \) in the sense of [Hai/l] Ass. 5.1] with respect to \( s \).
- For any \( \eta \in (-\infty,0) \setminus \mathbb{N} \), \( u \in C^\eta([0,1], T^d) \), \( k \in \mathbb{N}^{d+1} \), and for some \( \chi > 0 \), one has the bounds

\[
\sup_{t \in (0,1]} t^{-\eta/|k|/\bar{s}_0} \sup_{x \in T^d} \left| \int_{T^d} dy \, D^k G_t(t, x-y)u(y) \right| < \infty, \quad (2.7)
\]

\[
\sup_{|t| > 1} \sup_{x \in T^d} e^{\chi|t|} \left| (D^k G_t)(t, x) \right| < \infty. \quad (2.8)
\]

**Example 2.7** If \( \mathcal{L}_t = Q(\nabla_x) - 1 \) for a homogeneous polynomial \( Q \) of even degree \( 2q \) with respect to a scaling \( \bar{s} \), then [Hai/l] Lem. 7.4] implies that we can take \( |t|_{\bar{s}} = 2q \) for the scaling \( \bar{s} = (2q, \bar{s}_1, \ldots, \bar{s}_d) \). In particular, the heat operator with unit mass falls into this framework: here \( d = 1, s = (2,1,\ldots,1), \mathcal{L}_t = \Delta - 1 \), where \( \Delta \triangleq \sum_{j=1}^d \partial_j^2 \), and \( |t|_{\bar{s}} = 2 \). However, while this is the most common example, other non-trivial choices are possible: if one sets \( d = 2 \) and \( s = (4,2,1) \) then one can take \( \mathcal{L}_t \triangleq \partial_1^2 - \partial_2^2 - 1 \), and \( |t|_{\bar{s}} = 4 \).

**Remark 2.8** One can sharpen the second condition by assuming that for each \( t \in \Sigma^+ \), there exists \( \kappa_t > 0 \) such that (2.7) holds with \( t^{-\eta/|k|/\bar{s}_0} \kappa_t \) in place of \( t^{-\eta/|k|/\bar{s}_0} \). This could allow, in certain cases, for a lower regularity of initial data and/or driving terms. However, since \( \kappa_t = 1/\bar{s}_0 \) is optimal in most cases of interest, and since the current assumptions are already quite involved, we refrain from making this generalisation.

2.7 The local well-posedness theorem

We fix some quantities and objects just for the remainder of this subsection so we can state the aforementioned result.

We introduce a family of rooted decorated combinatorial trees \( \mathcal{J} \). An element \( \tau \in \mathcal{J} \) consists of an underlying combinatorial rooted tree \( T \) with node set \( N_T \), edge set \( E_T \), an edge decoration \( \hat{f} : E_T \to \emptyset \), and a node decoration \( \mathfrak{m} = (m^x, m^y) : N_T \to (\Sigma_0 \sqcup \{0\}) \times \mathbb{N}^{d+1} \). We also write \( \partial_T \in N_T \) for the root node and we sometimes write \( \tau = T^\mathfrak{m}_t \). Observe that for every \( \tau \in \mathcal{J} \) there exist unique \( n \geq 0, o_1, \ldots, o_n \in \emptyset \), and \( \tau_1, \ldots, \tau_n \in \mathcal{J} \) such that \( \tau \) is obtained by attaching each \( \tau_j \) to

---

\[\text{In particular, one could sharpen Lemma 6.5 below.}\]
the root of $\tau$ (which has some decoration $(l, k)$) using edges with decoration $o_j$. In this case we adopt the symbolic notation

$$\tau = X^k \Xi_l \left( \prod_{j=1}^n J_{o_j}[\tau_j] \right), \quad k \overset{\text{def}}{=} m^X(\varrho_T), \quad l \overset{\text{def}}{=} m^\Xi(\varrho_T). \quad (2.9)$$

In particular, when $n = 0$, so that $\tau$ consists of only the root node, we write $\tau = X^k \Xi_l$. Also, if $m^\Xi(\varrho_T) = 0$ or $m^X(\varrho_T) = 0$, then we omit the corresponding symbol $\Xi_0$ or $X^0$ respectively. Every tree of the form $\tau = J_o[\tau]$ for some $o$ and some $\tau$, we call planted.

For every $T^m_j \in \mathcal{F}$, we set

$$|T^m_j|_s \overset{\text{def}}{=} \sum_{e \in E_T} |f(e)|_s + \sum_{u \in N_T} (|m^\Xi(u)|_s + |m^X(u)|_s),$$

where $|0|_s \overset{\text{def}}{=} 0$.

For any $\tau$ and $F \in \tilde{\mathcal{Q}}$, we define $\mathcal{T}^F[\tau] \overset{\text{def}}{=} (\mathcal{T}^F[\tau])_{\tau \in \mathcal{L}^+} \in \mathcal{D}^{\mathcal{L}^+}$ inductively as follows. For $\tau$ given by (2.9) for some $n \geq 0$, we define for every $t \in \mathcal{L}^+$

$$\mathcal{T}^F_t[\tau] \overset{\text{def}}{=} \left( \prod_{j=1}^n \mathcal{T}^F_{t_j}[\tau_j] \right) \cdot \left( \partial^k \prod_{j=1}^n D_{o_j} \right) F^t_1,$$

where $o_j = (t_j, p_j)$.\n
**Definition 2.9** Given $t \in \mathcal{L}^+$, $F \in \tilde{\mathcal{Q}}$, and $\tau \in \mathcal{F}$ of the form (2.9), we say that $\tau$ is $t$-non-vanishing for $F$ if $(\partial^k \prod_{j=1}^n D_{o_j}) F^t_1 \neq 0$, and $\tau_j$ is $t_j$-non-vanishing for $F$ for all $j \in [n]$. Let $\mathcal{F}_t[F]$ denote the set of all $\tau \in \mathcal{F}$ that are $t$-non-vanishing for $F$. We also write $\mathcal{F}_m t[F] \subset \mathcal{F}[F]$ for those elements $\tau$ for which $|\tau|_s < 0$.

We note that, for every $\gamma \in \mathbb{R}$, and $t \in \mathcal{L}^+$, the set $\{ \tau \in \mathcal{F}_t[F] : |\tau|_s < \gamma \}$ is finite due to the local subcriticality of $F$ (see the proof of Theorem 2.3). In particular, $\mathcal{F}_m[F]$ is a finite set. Note also that if $\tau$ is not $t$-non-vanishing, then $\mathcal{T}^F_t[\tau] = 0$ but the converse implication is not true in general. With these notations, we consider the following assumption on $F \in \tilde{\mathcal{Q}}$, which is used in Section 6.3 to ensure that certain subspaces of a regularity structure form sectors.

**Assumption 2.10** For every $t \in \mathcal{L}^+$ and $T^m_j \in \mathcal{F}_t[F]$ and any strict subtree $T^m_j \subset T^m$ of $T$ with $|\varrho_T| = - |t|_s$, one has $|T^m_j|_s > - (|t|_s \wedge s_0)$.

---

3 This is because one can find $f_1, f_2 \in \mathcal{C}_0 \setminus \{0\}$ with $f_1 f_2 = 0$ because their supports are disjoint. However, the converse does hold for polynomial non-linearities.

4 By a subtree, we mean that $T^m_j$ is a tree whose node and edge sets are subsets of those of $T^m_j$ and whose decorations satisfy $f(e) = f(e)$ for all $e \in E_T$, and $m^\Xi(x) = m^\Xi(x)$ and $m^X(x) \leq m^X(x)$ for all $x \in N_T$. By a strict subtree, we mean $T^m_j \neq T^m_j$. 
2.7.1 The random driving terms

Given \( \varepsilon > 0 \), a smooth function \( \varrho : \Lambda \to \mathbb{R} \), and \( \psi \in \mathcal{S}'(\Lambda) \), we write
\[
\psi^{(\varepsilon)} \overset{\text{def}}{=} \psi \ast (S^\varepsilon \varrho).
\] (2.11)

Next we describe the class of driving noises included in our main theorem.

**Definition 2.11** We define Gauss to be the collection of all tuples \( \xi = (\xi_l)_{l \in \mathcal{L}} \) of jointly Gaussian, stationary, centred, random elements of \( \mathcal{S}'(\Lambda) \) which satisfy the following regularity properties for every \( l, l' \in \mathcal{L} \).

1. There exist distributions \( C_{l,l'} \in \mathcal{S}'(\Lambda) \) whose singular support is contained in \( \{0\} \) and with the property that for every \( f, g \in \mathcal{S}(\Lambda) \),
\[
E[\xi_l(f) \xi_{l'}(g)] = C_{l,l'} \left( \int_{\mathbb{R} \times \mathbb{T}^d} dz f(z - \cdot)g(z) \right).
\]

2. Writing \( z \mapsto C_{l,l'}(z) \) for the smooth function which determines \( C_{l,l'} \) away from 0, one has, for any \( g \in \mathcal{S}(\Lambda) \) satisfying \( D^k g(0) = 0 \) for all \( k \in \mathbb{N}^{d+1} \) with \( |k|_s < -|s| - |l|_s - |l'|_s \),
\[
C_{l,l'}[g] = \int dz C_{l,l'}(z)g(z).
\]

3. There exists \( \kappa > 0 \) such that for any \( k \in \mathbb{N}^{d+1} \)
\[
\sup_{0 < |z|_s \leq 1} |D^k C_{l,l'}(z)| : |z|_s^{-|l|_s - |l'|_s + |k|_s} < \kappa < \infty.
\]

It follows from Kolmogorov’s continuity theorem combined with items 1 and 3 above that every \( \xi \in \text{Gauss} \) admits a version which is a random element of \( \mathcal{C}^{\text{noise}} \defeq \bigoplus_{l \in \mathcal{L}} C^{|l|}_s(\Lambda) \).

2.7.2 The local existence theorem

Here and for the remainder of this subsection, we use the convention that for any collection \( \varphi = (\varphi_l)_{l \in \mathcal{L}} \) of smooth functions \( \varphi_l : \mathbb{R}^+ \times \mathbb{T}^d \to \mathbb{R} \) and \( z \in \Lambda \) we write
\[
\varphi(z) \defeq (\partial^p \varphi_l(z) : (t, p) \in \mathcal{O}) \in \mathbb{R}^\mathcal{O}.
\] (2.12)

We fix \( F \in \tilde{Q} \) for the remainder of this subsection. For every \( \xi \in \text{Gauss} \), our main result yields a (local in time) solution theory for the initial value problem
\[
\forall t \in \mathcal{L}_+, \quad \partial_t \varphi_t = \mathcal{L}(\varphi_t + F_t(\varphi)) + \sum_{l \in \mathcal{L}} F_l^t(\varphi)\xi_l,
\] (2.13)
with a suitably chosen initial condition \( \varphi_t(0, \cdot) \).
We now discuss where our solutions will live. In general our solution may not accommodate evaluation at fixed times, however we introduce a decomposition of our solution into a sum of explicit space-time distributions coming from perturbation theory, along with a remainder which is actually a function. The explicit perturbative part will live in the space

\[ C^{\text{reg},-} \equiv \bigoplus_{t \in \mathbb{L}_+} \left\{ \begin{array}{ll} C^{\text{reg}(t)}(A) & \text{if } \text{reg}(t) < 0, \\
{0} & \text{otherwise}. \end{array} \right. \]

In order to describe the remainder, we first set, for any \( t \in \mathbb{L}_+ \),

\[ \widetilde{\text{reg}}(t) \equiv |t|_s + \inf \{ |\tau|_s : \tau \text{ is t-non-vanishing and } |\tau|_s \geq -(|t|_s \land s_0) \}. \]

We then define, for any \( T \in (0, \infty) \), \( C^{\text{reg},+} \equiv \bigoplus_{t \in \mathbb{L}_+} C^{\text{reg}(t)}((0, T) \times \mathbb{T}^d) \).

We also define the spaces \( C^{\text{ireg}} \equiv \bigoplus_{t \in \mathbb{L}_+} C^{\text{reg}(t)}(\mathbb{T}^d) \), and \( \mathcal{C}^{\text{ireg}} \equiv C^{\text{ireg}} \cup \{ \infty \} \).

More precisely, we view \( C^{\text{reg}} \) as a Banach space with norm \( \| \cdot \|_{C^{\text{reg}}} \) and define the topological space \( \mathcal{C}^{\text{reg}} \) by including a point at infinity \( \infty \) and determining the topology by starting with the basis of open balls in \( C^{\text{reg}} \) and adding sets of the form \( \{ g \in C^{\text{reg}} : \| g \|_{C^{\text{reg}}} \geq N \} \cup \{ \infty \} \) for any \( N > 0 \). We adopt the notational convention that \( \| \infty \|_{C^{\text{reg}}} = +\infty \).

For any \( f \in C(\mathbb{R}_+, \mathcal{C}^{\text{reg}}) \) and \( L \in (0, \infty] \) we write

\[ T^L[f] \equiv \inf \{ t \in \mathbb{R}_+ : \| f(t) \|_{C^{\text{reg}}} \geq L \}, \quad T[f] \equiv T^\infty[f]. \]

Consider the space

\[ C^{\text{rem}} \equiv \left\{ f \in C(\mathbb{R}_+, \mathcal{C}^{\text{reg}}) : \forall t > T[f], \ f(t) = \infty \right. \left. f|_{(0, T[f])} \in C^{\text{reg},+}_{T[f]} \right\}. \]

Fix a smooth decreasing function \( \chi : \mathbb{R} \to \mathbb{R} \) which is identically 1 on \((-\infty, 0]\) and identically 0 on \([1, \infty) \). For any \( L \in \mathbb{N} \) we define a map \( \Theta_L : C^{\text{rem}} \to C(\mathbb{R}_+, \mathcal{C}^{\text{reg}}) \) by setting

\[ \Theta_L(f)(t) \equiv \chi \left( \frac{t - T^L[f]}{T^L[f] - T^L[f]} \right) f(t). \]

This is basically a “soft” way of stopping the function \( f \) when its norm becomes larger than \( L \). Note that \( \Theta_L(f) \in C^{\text{reg},+} \) for all \( T \geq 0 \) and \( f \in C^{\text{rem}} \). We equip \( C^{\text{rem}} \) with a metric \( d(\cdot, \cdot) \equiv \sum_{L=1}^{\infty} 2^{-L} d_L(\cdot, \cdot) \), where for \( f, g \in C^{\text{rem}} \)

\[ d_L(f, g) \equiv 1 \wedge \left[ \sup_{t \in [0, L]} \| \Theta_L(f)(t) - \Theta_L(g)(t) \|_{C^{\text{reg}}} + \| \Theta_L(f) - \Theta_L(g) \|_{C^{\text{rem},+}} \right]. \]

**Remark 2.12** The reason for the complicated definition of \( \Theta_L(f) \), rather than a simple stop such as \( \Theta_L(f)(t) \equiv f(t) \chi_{\{ t < T^L[f] \} + f(T^L(f)) \chi_{\{ t \geq T^L[f] \}} \), is that the latter loses time regularity, in which case it may happen that \( \| \Theta_L(f) \|_{C^{\text{rem},+}} = \infty \) (e.g., if \( \widetilde{\text{reg}}(t) > s_0 \) for some \( t \in \mathbb{L}_+ \)).
We also set

\[ C^{\text{class}} \equiv \left\{ f \in C(\mathbb{R}^+, \widehat{C^{\text{reg}}}) : \forall t > T[f], f(t) = \infty \right\}. \]

Finally, consider a smooth function \( \varrho : \mathbb{R}^{d+1} \to \mathbb{R} \) supported on the ball \( |z| \leq 1 \) with \( \int \varrho = 1 \), as well as a family of constants

\[ \{ c_{t, \varepsilon}^T \in \mathbb{R} : \tau \in \mathcal{F}_t \} \text{ for some } t \in \mathbb{Z} \cup \{ 0 \}. \quad (2.14) \]

We then denote by

\[ S_{\varrho, \varepsilon} : C^{\text{noise}} \times C^{\text{reg}} \to C^{\text{class}}, \quad S_{\varrho, \varepsilon} : (\xi, \psi) \mapsto \varphi_{\varepsilon} = (\varphi_{t, \varepsilon})_{t \in \mathbb{Z}} \]

the classical solution map of the following system of initial value problems for \( t \in \mathbb{Z} \)

\[ \partial_t \varphi_{t, \varepsilon} = \mathcal{L}(\varphi_{t, \varepsilon}) + \sum_{l \in \mathbb{Z}} F_l^t(\varphi_{t, \varepsilon}) + \sum_{\tau \in \mathcal{F}_t} c_{t, \varepsilon}^\tau \frac{Y^\tau_t(\varphi_{t, \varepsilon})}{S(\tau)}, \quad (2.15) \]

with initial data \( \varphi_{t, \varepsilon}(0, \cdot) \equiv \psi(\cdot) \), where the mollified noises \( \xi_t^{\varepsilon}(\cdot) \) are defined as in (2.11). The combinatorial symmetry factor \( S(\tau) \) appearing in this identity is defined as follows. For any tree \( \tau \) written as

\[ \tau = X^k \Xi \left( \prod_{j=1}^m J_{o_j} \beta_j \right), \]

where we group terms (uniquely) in such a way that \( (o_i, \tau_i) \neq (o_j, \tau_j) \) for \( i \neq j \), we inductively set

\[ S(\tau) \equiv k! \left( \prod_{j=1}^m S(\tau_j)^{\beta_j} \beta_j ! \right). \quad (2.16) \]

In order to formulate our result, it will be convenient to decompose the map \( S_{\varrho, \varepsilon} \) into a stationary part

\[ S_{\varrho, \varepsilon}^- : C^{\text{noise}} \to C^{\text{reg}}, \quad S_{\varrho, \varepsilon} : \xi, \psi \mapsto S_{\varrho, \varepsilon}^- (\xi) + S_{\varrho, \varepsilon}^+ (\xi), \]

independent of the initial condition, as well as a part

\[ S_{\varrho, \varepsilon}^+ : C^{\text{noise}} \times C^{\text{reg}} \to C^{\text{class}}, \]

which does depend on the initial condition. These two maps will be chosen in such a way that one has the identity

\[ S_{\varrho, \varepsilon} (\xi, \psi) = S_{\varrho, \varepsilon}^- (\xi) + S_{\varrho, \varepsilon}^+ (\xi) \]

(2.17)

Here \( S_{\varrho, \varepsilon}^- (\xi) \) is a function of space obtained by restricting \( S_{\varrho, \varepsilon}^+ (\xi) \) to the time 0 hyperplane. We also remark that addition between an element of \( C^{\text{class}} \) and an element of \( C^{\infty} \) naturally yields again an element of \( C^{\text{class}} \).
The precise definitions of $S_{\varepsilon}^{\pm}$ will be given in Section \ref{sec:construction}, below, based on the construction of Section \ref{sec:construction} below, but do not matter much at this stage. Suffices to say that this decomposition should be thought of as a higher order version of the classical Da Prato–Debussche trick \cite{DPD1, DPD2}.

With all of these preliminaries in place, our general convergence result can be formulated as follows.

**Theorem 2.13** Suppose that Assumptions \ref{ass:main} and \ref{ass:main} hold and that, for every $t \in \mathbb{Z}_+$ and $T_t^m \in \mathcal{F}$ with $|E_T| > 0$, one has

\[
|T_t^m|_s - \max_{x \in N_T^{\varepsilon}} |m (x)|_s > 0 , \quad |T_t^m|_s > -\frac{|s|}{2} , \quad |T_t^m|_s + |s| + \min_{t \in \mathbb{Z}_-} |t|_s > 0 .
\] (2.18)

Let $\xi \in \text{Gauss}$, viewed as a $C^{\text{noise}}$-valued random variable. Then the system \ref{eq:main} admits maximal solutions in the following sense. There exist maps $S^{-} : C^{\text{noise}} \to C^{\text{reg}}$ and $S^{+} : C^{\text{noise}} \times C^{\text{reg}} \to C^{\text{rem}}$ with the following properties.

- The maps $S^{\pm}$ are measurable.
- For almost every $\xi$, the map $\psi \mapsto T[S^{+}(\xi, \psi)]$ is a strictly positive lower semicontinuous function and $\psi \mapsto S^{+}(\xi, \psi)$ is continuous from $C^{\text{reg}}$ into $C^{\text{rem}}$.
- For any smooth function $\varphi : \mathbb{R}^{d+1} \to \mathbb{R}$ supported on the unit ball with $\int \varphi = 1$, there exists a choice of constants \ref{eq:constants} such that, as $\varepsilon \downarrow 0$, $S_{\varepsilon}^{\varphi}$ converges to $S^{-}$ in probability as random elements of $C^{\text{reg}}$ and, for fixed $\psi \in C^{\text{reg}}$, $S^{+}_{\varepsilon}(\xi, \psi)$ converges in probability to $S^{+}(\xi, \psi)$ as random elements of $C^{\text{rem}}$.

A possible choice for the constants \ref{eq:constants} is given by

\[
\begin{equation}
\begin{split}
c_{\varepsilon}^\tau &= E[\Pi_{\varepsilon}^{\tau} \tilde{A}_k^{\tau}(0)] ,
\end{split}
\end{equation}
\] (2.19)

where $\tilde{A}_k^{\tau}$ is the twisted antipode defined in \cite{BHZ1, Prop. 6.17} and $\Pi_{\varepsilon}^{\tau}$ is the canonical lift of $(\xi^{(e)}_t)_{t \in \mathbb{Z}_-}$ defined in \cite{BHZ1, Sec. 6.2}. In particular, $c_{\varepsilon, \varphi}^\tau$ can be taken as zero whenever $\tau$ is planted or of the form \ref{eq:form} with $k \neq 0$.

**Remark 2.14** The first condition of \ref{eq:main} is in fact automatic for locally subcritical systems of SPDEs where all driving noises have the same regularity. In the general case, this condition is more for convenience than a fundamental necessity. This assumption was also made in \cite{CH1} to ease the presentation of the proof. If this condition fails, one can always rewrite the system under consideration in such a way that it is satisfied for the rewritten (equivalent) system. We also mention that our formulation of the renormalised equation in \ref{eq:renormalised} is based on this assumption. Our main theorem, which is a combinatorial / algebraic result, does not require this condition and in the more general case one may see new terms involving components of the noises $\xi$ in the renormalised equation – see Section \ref{sec:combinatorial}.
The second condition of (2.18) guarantees that none of the stochastic objects we need to control have diverging variances. Diverging variances cannot be cancelled by the subtraction of renormalisation constants and thus fall outside of our framework. The difficulty of dealing with this scenario was already observed in [CQ02, FV10, Hos10, HHL+15, CH16] and one can not expect the conclusions of Theorem 2.13 to hold in this case. The third condition likewise prevents the occurrence of divergences we cannot renormalise.

Remark 2.15 The statement of Theorem 2.13 is more convoluted than a classical maximal existence theorem due to our splitting of the solution map into maps \( S^- \) and \( S^+ \). This is because our method of proof is to solve an equation for the remainder term of a truncated perturbative expansion at stationarity. This truncated expansion is given by \( S^- \), which can be written explicitly as a finite sum of renormalised multilinear functionals of \( \xi \). Each such functional makes sense as a global in time object and there is one such functional for every \( t \)-non-vanishing tree \( T^m_t \) with \( |T^m_t| \leq -(|t| \wedge s_0) \). The remainder, which may blow up in finite time, is then given by \( S^+(\psi) \).

The generality allowed by the assumptions of Theorem 2.13 means that this notion of maximal solution is the best one can hope for. This is also needed for treating equations with scaling behaviour like the dynamical \( \Phi^4_d \) problem with \( d \geq 3 \). Indeed, our result then applies as stated for arbitrary (non-integer) \( d < 4 \) for which it is not possible to find a function space \( B \) containing typical realisations of the solutions and such that even the deterministic Allen-Cahn equation is well-posed for arbitrary initial data in \( B \).

2.8 Applications

2.8.1 The generalised KPZ equation

We apply Theorem 2.13 to the generalised KPZ equation as described in Section 2.4. We note that the convergence statement of Theorem 2.13 simplifies greatly in this example since, as we shall see below, there are no \( t \)-non-vanishing trees with \( |T^m_t| \leq -(|t| \wedge s_0) \), so by Remark 2.15 one can take \( S_{\theta, \varepsilon}^- (\xi) = S^- (\xi) = 0 \).

For every \( t \in \mathfrak{L}_+ \), we set \( \mathcal{L}_t \equiv \partial_t^2 - 1 \). Note that we chose \( \mathcal{L}_t \) to satisfy (2.8), and added the term \( \mathcal{I}_{t(0)} \) to \( F^1 \) accordingly.

We define \( \text{reg} : \mathcal{L} \to \mathbb{R} \) and \( \text{ireg} : \mathcal{L}_+ \to \mathbb{R} \) by \( \text{reg}(t) = \text{ireg}(t) = \frac{1}{2} - 3\kappa \) for \( t \in \mathcal{L}_+ \), and \( \text{reg}(t) = -3/2 - 2\kappa \) for \( t \in \mathcal{L}_- \). Then it is straightforward to check that \( F \) obeys \( \text{reg} \) in the sense of Definition 2.7. Note also that Assumption 2.10 trivially holds, while Assumption 2.4 is readily verified upon noting that \( n_t = |t| \wedge (2 \text{ireg}(t) - 2) = (-\frac{3}{2} - \kappa) \wedge (-1 - 6\kappa) \).

We turn to checking the conditions (2.18). As mentioned in Remark 2.14, the first condition follows from the fact that \( F \) obeys \( \text{reg} \) and \( |t| \wedge \) is constant on \( \mathcal{L}_- \). The second and third conditions are immediate consequences of the easily proven fact.

\footnote{See the proof of Theorem 2.13 in Section A.5}
that for any \( T^m \in \mathcal{R}_i \cdot [F] \) with \( |E_T| > 0 \) one has \( |T^m| \geq -1 - 2\kappa > -\frac{3}{2} + \kappa \). It follows that one can apply Theorem 2.13 to the generalised KPZ equation with the further simplification that \( S_{\kappa,\varepsilon} (\xi) = S^\varepsilon (\xi) = 0 \) as claimed.

We finish this subsection by performing explicit computations of some of the terms \( \mathcal{Y}_t^F [T^m] \) and constants \( c_{\kappa,\varepsilon} [T^m] \) appearing on the RHS of the renormalised equation for \( u_\varepsilon = (u_{i,\varepsilon})_{i=1}^M \). There is a degree of freedom in choosing \( c_{\kappa,\varepsilon} [\cdot] \) as given in (2.19), in that in order to specify \( \Pi^{\kappa,\varepsilon} \) one must fix a choice of truncation of \((\partial_0 - \mathcal{L})^{-1}\) for each \( t \in \mathbb{R}_+. \) For convenience, since all these kernels coincide in our case, just fix a single kernel \( K(z) \) which is a smooth function on \( \Lambda \setminus \{0\} \) that is of compact support, agrees with \((\partial_0 - \mathcal{L})^{-1}\) for \(|z|_8 \leq 1\), and integrates to 0.

Let us consider the trees given by \( \mathcal{J}_{(j,0)}(X^{0,1}) = \mathcal{J}_{(j,0)}(\Xi) \mathcal{J}_{(k,(0,1))}(\Xi) \) in the notation of [22]. Both trees are of homogeneity \(-2\kappa\) and we can depict them graphically as in [23] by

\[
\mathcal{J}_{(j,0)}(X^{0,1}) = e_t, \quad \mathcal{J}_{(j,0)}(\Xi) \mathcal{J}_{(k,(0,1))}(\Xi) = e_{\mathcal{J}}.
\]

(We suppress the indices in the graphical notation for the sake of conciseness. Circles represent instances of \( \Xi \), the cross represents the factor \( X^{(0,1)} \).) We first walk through the computation of \( \mathcal{Y}_t^F [e_t](u) \) for some arbitrary \( t \in \mathbb{R}_+ \):

\[
\begin{align*}
\mathcal{Y}_t^F [e_t](u) &= F_t^e (u) = \sigma_t^e (u) \\
\mathcal{Y}_t^F [\varepsilon](u) &= (\partial^{(0,1)} \mathcal{Y}_t^F [\varepsilon])(u) = (\partial^{(0,1)} F_t^e)(u) = \sum_{l=1}^M (\partial_x u_l) (D_l \sigma_t^e)(u) \\
\mathcal{Y}_t^F [e_{\mathcal{J}}](u) &= (\mathcal{Y}_j [\varepsilon] D_{(j,0)} F_t^e)(u) \\
&= (D_j \sigma_t^e)(u) \sum_{l=1}^M (\partial_x u_l) (D_l \sigma_t^e)(u). \\
\end{align*}
\]

Using formula (2.19) we get:

\[
c_{\kappa,\varepsilon} [e_t] = E[(\Pi^{\kappa,\varepsilon} \mathcal{J}_{(j,0)}(\Xi)) (0)] = -E[(\Pi^{\kappa,\varepsilon} \varepsilon)(0)] \tag{2.20}
\]

\[
= \int_{\Lambda^2} \varrho_{\varepsilon}(z - z') \varrho_{\varepsilon}(-z') z_1 K(-z) \, dz \, dz'.
\]

For the tree \( e_{\mathcal{J}} \) we have

\[
\begin{align*}
\mathcal{Y}_t^F [e_{\mathcal{J}}](u) &= [\mathcal{Y}_j^F [\varepsilon] \mathcal{Y}_t^F [\varepsilon] D_{(j,0)} D_{(k,(0,1))} F_t^0](u) \\
&= \sigma_t^e(u) \sigma_k^e(u) \sum_{l=1}^M (\partial_x u_l) (D_j (\Gamma_{w,k} + \Gamma_{k,w}^l))(u)
\end{align*}
\]

and, writing \( K^{(\kappa,\varepsilon)} \overset{\text{def}}{=} K * \varrho_{\varepsilon} \),

\[
c_{\kappa,\varepsilon} [e_{\mathcal{J}}] = E[(\Pi^{\kappa,\varepsilon} \mathcal{J}_{(j,0)}(\Xi)) (0)] = -E[(\Pi^{\kappa,\varepsilon} \mathcal{J}_{(j,0)}(\Xi)) (0)]
\]
We fix some $1 + 4$ dimensions $\Lambda \defeq \mathbb{R} \times T^4$ and use the parabolic scaling $s = (2, 1, 1, 1, 1)$. We work here in $1 + 4$ dimensions $\Lambda \defeq \mathbb{R} \times T^4$ and use the parabolic scaling $s = (2, 1, 1, 1, 1)$. We fix some $\delta > 0$ and consider $\xi$ as a Gaussian noise which satisfies the conditions of Definition $2.11$ for every $\|l\| < -3 + \frac{\delta}{2}$ (constructed, for example, by the convolution of white noise on $\Lambda$ with a slightly regularising kernel).

Note that, in terms of scaling properties, the cases $\delta = 2$ and $\delta = 1$ behave like the usual $\Phi^4_2$ [DDP03] and $\Phi^4_3$ [CC13, Hai14, HX16, MW16] equations respectively, while the case $\delta = 0$ corresponds to the critical regime.

In this example, we demonstrate a situation where one is unable to start the equation from initial data of the “natural regularity”, i.e., of the same regularity as the solution, and thus requires the full power of Assumptions $2.4$ and $2.10$ and the decomposition of $\mathcal{S}$ into $\mathcal{S}^\pm$ in Theorem $2.13$. As we shall see below, for every $\delta > 0$, one must take $\varphi_\epsilon(0, \cdot) = \psi + \mathcal{S}^\epsilon_{\varphi_\epsilon}(0, \cdot)$ where $\psi \in C^0_b(T^d)$ with $\eta > \left(-\frac{2}{3}\right) \lor (-\delta)$, and $\mathcal{S}^\epsilon_{\varphi_\epsilon}$ is the explicit perturbative part which converges in $C_{s}^{-1+\delta/2-\kappa}(\Lambda)$ in probability as $\varepsilon \to 0$. In particular, rougher noise forces us to start the equation from a smoother initial condition for the remainder (which can be interpreted as starting the equation closer to equilibrium).

Remark 2.16 One can see directly the necessity of the lower bound $\eta > -\frac{2}{3}$ by recalling that the deterministic map which sends $\varphi(0, \cdot)$ to the solution $\varphi(0, \cdot)$ with zero noise $\xi = 0$ is continuous only for $\varphi(0, \cdot) \in C^0_b(T^d)$ with $\eta > -\frac{2}{3}$, cf. [Hai14, Rem. 9.9].

We fix some $\delta > 0$ and $\kappa \in (0, \frac{\delta}{2})$ for the rest of the example. First, a computation shows that the renormalised equation takes the form

$$\partial_t \varphi_\epsilon = (\Delta - 1)\varphi_\epsilon - \varphi_\epsilon^3 + C_{\epsilon,2}\varphi_\epsilon^2 + C_{\epsilon,1}\varphi_\epsilon + C_{\epsilon,0} + \sum_{i=1}^{4} C^{(i)}_{\epsilon} \partial_i \varphi_\epsilon + \xi(\epsilon). \quad (2.23)$$

Indeed, here $\Sigma_+ = \{t\}$ and $\Sigma_- = \{t\}$ are singletons, $\|l\|_a = 2$, and $\|l\|_a \defeq -3 + \frac{\delta}{2} - \kappa$. The corresponding non-linearity is the cubic function $F(\mathcal{X}) = \mathcal{X}^3$. Suppose that $\tau = \mathcal{T}^m \in \mathcal{S}_{-1}[F]$ has at least one edge, i.e. it is not of the form $\Xi_1$. The following can readily be deduced by an inductive argument: if $x \in N_T$ is a leaf, then $m^x(x) = 1$; if $x \in N_T$ is not a leaf, then $m^x(x) = 0$; if $e \in E_T$, then $f(e) = (t, 0)$. Moreover, every node $x \in N_T$ must have $m^x(x) = 0$ and, if $x$ is not a leaf, must have three outgoing edges with the following possible exceptions:
1. there is exactly one node with one outgoing edge; in this case $|\tau|_s = -1 + \frac{\delta}{2} - \kappa$ if $\tau$ is the planted tree $\mathcal{F}(t_0)[\Xi]$, and $|\tau|_s \geq -1 + \frac{3}{4}\delta - 3\kappa$ otherwise,
2. there is exactly one node $x$ with two outgoing edges and $m^x(x) = e_i$ for some $i = 1, \ldots, 4$; in this case $|\tau|_s = -1 + \delta - 2\kappa$ if $\tau = \mathbf{X}^i \mathcal{F}(t_0)[\Xi]^2$, and $|\tau|_s \geq -1 + 2\delta - 4\kappa$ otherwise,
3. there are exactly two nodes with two outgoing edges each; in this case $|\tau|_s \geq -1 + \frac{5}{2}\delta - 3\kappa$.
4. there is exactly one node with two outgoing edges; in this case $|\tau|_s \geq -2 + \delta - 2\kappa$,
5. no exceptions; in this case $|\tau|_s \geq -3 + \frac{3}{2}\delta - 3\kappa$.

An inductive argument tells us that the counterterms associated to the above possibilities are given respectively by (up to combinatorial factors):

1. $\varphi^2_\epsilon$
2. $\partial_i \varphi_\epsilon$
3. $\varphi^2_\epsilon$
4. $\varphi_\epsilon$
5. a numeric constant.

Furthermore, recalling that planted trees and trees with polynomial decorations at the root do not contribute to the counterterms, we see that $C_{\epsilon,2} \varphi^2_\epsilon$ and $C^{(i)}(\partial_i \varphi_\epsilon)$ do not appear in $\mathcal{L}_{\epsilon}$ whenever $\delta > \frac{3}{2}$ and $\delta > \frac{1}{2}$, respectively, which explains their absence in the usual $\Phi^4_3$ equation. Similarly, $C_{\epsilon,1} \varphi_\epsilon$ and $C_{\epsilon,0} \varphi_\epsilon$ do not appear whenever $\delta > 2$, precisely the values for which $\mathcal{L}_{\epsilon}$ is classically well-posed. Note further that, due to the symmetry $\varphi \mapsto -\varphi$, one can in fact take $C_{\epsilon,2} = C_{\epsilon,0} = 0$ since our noise has vanishing odd moments.

**Remark 2.17** Equation (2.22) also demonstrates an example where the naive rule constructed from the corresponding non-linearity is not complete in the sense of [BHZ16]. Indeed, the rule $R(t) = \{0\}$, $R(t) = \{\Xi\}$, $(\mathcal{F}(t_0)[\lambda])_{\lambda = 0, \ldots, 3}$ ceases to be complete for $\delta \leq \frac{1}{2}$, and its completion [BHZ16, Def. 5.21] is given by adding $\{(\mathcal{F}(t_0))[\lambda]\}_{\lambda = 1, \ldots, 4}$ to $R(t)$. While the consideration of rules is not necessary to compute the renormalised equation, we note that $R$ fails to be complete for the same reason as the counterterm $\sum_{i=1}^4 C^{(i)}(\partial_i \varphi_\epsilon)$ appears in $\mathcal{L}_{\epsilon}$ which are consequences of the (negative) renormalisation procedure.

Continuing on, we define $\text{reg} : \mathcal{L} \to \mathbf{R}$ by $\text{reg}(t) \overset{\text{def}}{=} -3 + \frac{3}{2}\delta - 2\kappa$ and $\text{reg}(t) \overset{\text{def}}{=} -1 + \frac{5}{2}\delta - 3\kappa$ since $\text{reg}(t) > -1$, we see that $\mathcal{F}$ obeys reg, i.e., the equation (2.22) is subcritical. Furthermore, choosing any $\text{ireg} : \mathcal{L}_+ \to \mathbf{R}$ such that $\text{ireg}(t) > (-2/3) \lor (-\delta + 6\kappa)$, we see that Assumption (2.4) is satisfied. Indeed, the first condition in Assumption (2.4) is trivial since $\delta_+ = \emptyset$. Furthermore, using Remark (2.3) we have that $n_t = |0|_s + (3 \text{ireg}(t)) \lor (\text{ireg}(t) + 2 \text{reg}(t))$. Hence the bounds in the second condition of Assumption (2.4) are respectively equivalent to

$$(3 \text{ireg}(t)) \lor (\text{ireg}(t) + 2 \text{reg}(t)) > -2 \iff \text{ireg}(t) > (-2/3) \lor (-\delta + 6\kappa),$$

both of which are satisfied with the above choices. Note that the first condition of (2.18) is again automatic by Remark (2.14) while the second and third condi-
tions of (2.18), as well as Assumption 2.19 are readily checked using the above classification of $\mathcal{J}'_{\varepsilon}[F]$. We thus meet all the criteria to apply Theorem 2.13.

To summarise, it follows from Theorem 2.13 that for any fixed $\delta > 0$ there exists
- a choice of constants $C_{\varepsilon,2}, C_{\varepsilon,1}, C_{\varepsilon,0}, C_{\varepsilon}^{(i)}$, $i = 1, \ldots, 4$, and
- a function of the noise $S_{\varepsilon}^-(\xi)$ which is smooth for every $\varepsilon > 0$,

such that, as $\varepsilon \downarrow 0$,
- $S_{\varepsilon}^-(\xi) \rightarrow S^-(\xi)$ in $C_\delta^{-1+\delta/2-\kappa}(\Lambda)$ in probability, and
- for any $\eta > (-\frac{\delta}{2}) \vee (-\delta)$, the solution to the renormalised equation (2.23) with initial condition $\varphi_\varepsilon(0, \cdot) = \psi + (S_{\varepsilon}^-(\xi))(0, \cdot)$, for fixed $\psi \in C_\delta^{\eta}(T^d)$, converges in probability to local solutions in the sense dictated by the theorem.

Remark 2.18 In the case $\delta \in (\frac{\delta}{4}, 2]$, the perturbative part $S^-$ takes on the simple form $S_{\varepsilon}^-(\xi) \overset{\text{def}}{=} G * \xi(0, \varepsilon) \rightarrow S^-(\xi) \overset{\text{def}}{=} G * \xi$, where the convergence moreover happens in the space $C([0, T], C_\delta^{-1+\delta/2-}(T^d))$ (cf. [Hai14] Sec. 9.4). One can leverage this fact to build a more explicit (though equivalent) solution theory for the $\Phi^4_3$ equation than that given by Theorem 6.7.

3 Algebraic theory and main theorem

3.1 Set-up of the regularity structure and renormalisation group

We freely use the notion of rules and relation notation from [BHZ16] Sec. 5.2. We start by fixing a normal complete rule $R$ which is subcritical with respect to $\text{reg} : \mathcal{L} \rightarrow \mathbb{R}$; namely

$$\text{reg}(t) < |t|_\mathcal{N} + \inf_{N \in R(t)} \sum_{(b, p) \in N} \text{reg}(b, p), \quad \forall t \in \mathcal{L}.$$  

We denote by $\mathcal{J} \overset{\text{def}}{=} (\mathcal{J}^\text{ex}, G)$ the (untruncated) extended regularity structure corresponding to $R$ as defined in [BHZ16], and by $\mathfrak{R}$ the corresponding renormalisation group [11]. We write $T^\text{ex}$ for the collection of decorated trees which span $\mathcal{J}^\text{ex}$. These decorated trees are of the form $T^\varepsilon_{\varepsilon}^{n, o}$, where $T$ is a rooted tree endowed with a type map $t : E_T \rightarrow \mathcal{L}$, an edge decoration $e : E_T \rightarrow \mathbb{N}^{d+1}$ and two node decorations $n : N_T \rightarrow \mathbb{N}^{d+1}$, $o : N_T \rightarrow \mathbb{Z}^{d+1} \oplus \mathcal{Z}(\mathcal{L})$. We assign to any such tree two degrees $| \cdot |_-$ and $| \cdot |_+$ by

$$|T^\varepsilon_{\varepsilon}^{n, o}|_- \overset{\text{def}}{=} \sum_{e \in E_T} (|t(e)|_\mathcal{L} - |e|_\mathcal{L}) + \sum_{x \in N_T} |n(x)|_\mathcal{L},$$

$$|T^\varepsilon_{\varepsilon}^{n, o}|_+ \overset{\text{def}}{=} \sum_{e \in E_T} (|t(e)|_\mathcal{L} - |e|_\mathcal{L}) + \sum_{x \in N_T} (|n(x)|_\mathcal{L} + |o(x)|_\mathcal{L}). \quad (3.1)$$

At this stage we really mean the full renormalisation group $\mathfrak{R}$ which gives complete freedom on how to treat extended labels, we are not restricting to the subgroups mentioned in [BHZ16] Rem. 6.25.
Given a rooted tree \( T \), we endow \( N_T \) with the partial order \( \leq \) where \( x \leq y \) if and only if \( x \) is on the unique path connecting \( y \) to the root.

We write \( \mathfrak{M} \) for the set of linear maps \( M : \mathcal{T}^{\text{ex}} \to \mathcal{T}^{\text{ex}} \) of the form \( M_g \) for some \( g \in \mathcal{G}^{\text{ex}} \), see [BHZ16 Sec. 6.3].

### 3.2 Drivers

Our equations will be written in a mild formulation, where we ask for the components of the solution to be equal to an integral kernel operator acting on a linear combination of elements of \( \mathcal{P} \) multiplied by “driving terms”. The family of possible driving terms includes the noises and their derivatives \( \{ D^e \xi_t : t \in \Lambda_- , \ e \in \mathbb{N}^{d+1} \} \), products of such terms, as well as the constant function 1. In order to incorporate information on how an equation has been renormalised, it is natural to allow for some degeneracy in the set of drivers in our abstract formulation, so we introduce some notation for this. First, we define \( \hat{\mathcal{D}} \overset{\text{def}}{=} \{ (l, e) : l \in \Lambda_- , \ e \in \mathbb{N}^{d+1} \} \). Then we define

\[
\hat{\mathcal{D}} \overset{\text{def}}{=} \left\{ \hat{l} \in \mathcal{N}^{\hat{\mathcal{D}}} : \exists t \in \Lambda_+ \text{ with } \Xi_{\hat{l}} \in R(t) \right\} ,
\]

where, for \( \hat{l} = \{ (l_1, e_1), \ldots , (l_k, e_k) \} \in \hat{\mathcal{D}} \), we set

\[
\Xi_{\hat{l}} \overset{\text{def}}{=} D^{l_1} \Xi_{e_1} \cdots D^{l_k} \Xi_{e_k} \in \mathcal{T}^{\text{ex}},
\]

with the product being the tree product in \( \mathcal{T}^{\text{ex}} \). In particular, \( \Xi_0 = 1 \). Note that subcriticality of \( R \) implies that \( \hat{\mathcal{D}} \) is finite and that, by completeness, one has 0 \( \in \hat{\mathcal{D}} \).

We also define, as in [BHZ16 Def. 5.22], a set \( D(t, N) \subset \mathbb{Z}_+ + \mathbb{Z}(\mathcal{L}) \) of extended decorations for every \( t \in \Lambda_+ \) and \( N \in R(t) \). We extend this definition by setting \( D(t, N) = \emptyset \) for \( t \in \Lambda_+ \) and \( N \in N \setminus R(t) \) where \( N \) is the set of all possible node types as in [BHZ16 Sec. 5.2].

For each \( t \in \Lambda_+ \) we define a corresponding set of drivers \( \mathcal{D}_t \) via

\[
\mathcal{D}_t \overset{\text{def}}{=} \{ (\hat{l}, \circ) : (l, \circ) \in \hat{\mathcal{D}} \times (\mathbb{Z}_+ + \mathbb{Z}(\mathcal{L})) : \circ \in D(t, \hat{l}) \} .
\]

We also write \( \mathcal{D} = \bigcup_{t \in \Lambda_+} \mathcal{D}_t \). For \( l = (l, \circ) \in \mathcal{D} \) we use as above the shorthand

\[
\Xi_{l} \overset{\text{def}}{=} \Xi_{\hat{l}} \cdot \circ^{0, \circ} \in \mathcal{T}^{\text{ex}}, \ |l|_+ \overset{\text{def}}{=} |\Xi_l|_+ .
\]

### 3.3 Inner product spaces of trees

#### 3.3.1 A general construction

We introduce a very general prescription for building inner products of rooted decorated trees which is designed to have the advantage of automatically encoding symmetry factors of trees\(^{11}\)

\(^{11}\)The situation focused on in this paper is the “fully commutative”, in particular we see the degree 1 polynomials \( (X^\circ)^{l=0} \) as commuting and also do not distinguish different planar embeddings of trees (i.e., we assume \( \mathcal{J}_d(\tau) \) and \( \mathcal{J}_d(\tau') \) also commute). One key advantage of the formalism we adopt here is that it allows our work to be more easily translated to situations where some of this commutativity is lost, for instance [GH17b], by a simple tweak of the construction given here.
Saying that a set of rooted trees are decorated means that that there are different species of nodes and edges appearing in our trees. We thus assume that we are given a set \( N \) of possible node species and another set \( E \) of possible edge species. We write \( D = (N, E) \) for the tuple of decorations. We also assume we have been given an inner product \( \langle \cdot, \cdot \rangle \) on the free vector space generated by \( N \).

We will generate a corresponding set of rooted decorated trees \( T(D) \) and an inner product space built from the free vector space generated by \( T(D) \) and extending \( (\bullet) \) which we will call \( \mathcal{I}(D) \). We write \( Y \) for an element of \( N \). We write \( I \) for an element of \( E \), and each such element will be thought of as operator on \( T(D) \). In particular we view the full set \( T(D) \) as being generated from the set of nodes by taking products and applying the edge operators. We recall how our symbolic definition of a rooted decorated tree corresponds to the naive one. Given \( n \geq 0 \), \( I_1, \ldots, I_n \in E \), a collection of previously defined rooted decorated trees \( \tau_1, \ldots, \tau_n \), and \( Y \in N \), the rooted decorated tree

\[
\tau = Y \prod_{i=1}^{n} I_i(\tau_i)
\]  

(3.4)
is obtained as follows:

- Start with the trees \( \tau_1, \ldots, \tau_n \) and add a new node of type \( Y \).
- For each \( 1 \leq i \leq n \) connect the new node to the root of \( \tau_i \) with an \( I_i \) edge.
- Make the new node the root.

We treat the product over \([n]\) appearing in (3.4) as commutative.

We will define \( T(D) \) defined by \( \bigcup_{k=0}^{\infty} T_k(D) \) and now define the sets on the RHS. For \( k = 0 \) we set \( T_0(D) \) is identified with \( N \). Then for \( k \geq 1 \) and \( l \geq 0 \) we define \( T_k^{(l)}(D) \) inductively by setting \( T_k^{(0)}(D) = \emptyset \) and then setting, for \( l \geq 1 \), \( T_k^{(l)}(D) \) to be given by all elements \( \tau \) of the form (3.4) where one takes \( n = k \) and requires \( \tau_1, \ldots, \tau_k \in T^{(l-1)}(D) \) where we set

\[
T_k^{(l-1)}(D) \equiv T_0(D) \cup \left( \bigsqcup_{k \geq 1} T_k^{(l-1)}(D) \right).
\]

Finally, we set \( T_k(D) \equiv \bigcup_{l \geq 0} T_k^{(l)}(D) \). Similarly, we define

\[
\mathcal{I}(D) \equiv \bigoplus_{k \geq 0} \mathcal{I}_k(D)
\]

where, for each the \( k \geq 0 \), \( \mathcal{I}_k(D) \) is an inner product space with its underlying vector space being the free vector space generated by \( T_k(D) \).

**Remark 3.1** The space \( \mathcal{J} \) is of the form \( \mathcal{I}(D) \) with \( N = (\Sigma_+ \sqcup \{0\}) \times \mathbb{N}^{d+1} \) and \( E = \emptyset \). (In our notations, \( N \) is identified with \( \{X^k \xi_l : k \in \mathbb{N}^{d+1}, l \in \Sigma_+ \sqcup \{0\}\} \).

For \( k = 0 \) the inner product for \( \mathcal{I}_0(D) \) is given by the one given as input for our
construction. For \( k \geq 1 \) we inductively set, for any \( \tau, \bar{\tau} \in T^k(D) \),

\[
\langle \tau, \bar{\tau} \rangle \overset{\text{def}}{=} (Y, \bar{Y}) \prod_{s \in S_k} \delta_{I_j, \bar{I}_{sj}} \langle \tau_j, \bar{\tau}_{sj} \rangle
\]

where \( S_k \) is the set of permutations on \([k]\) and we are using \( Y \) (resp. \( \bar{Y} \)), \( I_j \) (resp. \( \bar{I}_j \)), and \( \tau_j \) (resp. \( \bar{\tau}_j \)) as those appearing in (3.4) for the expansion of \( \tau \) (resp. \( \bar{\tau} \)).

One should remember that \( T(D) \) is an orthogonal but not orthonormal basis for \( \mathbb{T}(D) \). We often write expansions of \( \sigma \in \mathbb{T}(D) \) in the dual basis \((\langle \tau, \tau \rangle^{-1} \tau : \tau \in T(D)) \) as \( \sigma = \sum_{\tau \in T(D)} \langle \sigma, \tau \rangle \langle \tau, \tau \rangle^{-1} \).

The construction above also enjoys some natural functorial properties.

**Lemma 3.2** Suppose we are given two sets of decorations \( D = (N, E) \) and \( D' = (N', E) \) along with inner products on \( \langle N \rangle \) and \( \langle N' \rangle \). Then for any linear operator \( A : \langle N \rangle \rightarrow \langle N' \rangle \) we define a linear operator \( \mathbb{T}_{D,D'}(A) : \mathbb{T}(D) \rightarrow \mathbb{T}(D') \) as follows. For any \( \tau \in T(D) \), we inductively set

\[
\mathbb{T}_{D,D'}(A) \tau = (AY) \prod_{i=1}^{n} I_i(A\tau_i),
\]

where on the RHS we have used the expansion (3.4).

Then if we denote by \( A^* : \langle N' \rangle \rightarrow \langle N \rangle \) the adjoint of \( A \) (defined with respect to the given inner products on \( \langle N \rangle \) and \( \langle N' \rangle \)) then \( \mathbb{T}_{D,D'}(A^*) \), the adjoint of \( \mathbb{T}_{D,D'}(A) \), is given by \( \mathbb{T}_{D',D}(A^*) \).

### 3.3.2 The trees of \( V \)

We introduce a new notation for rooted decorated combinatorial trees, closely related to the notation of Section 2.7. Let \( V \) be the set of all decorated trees of the form \( T^m_I \) where \( m = (m_e, m_x) : N_T \rightarrow D \times \mathbb{N}^{d+1} \) and \( f : E_T \rightarrow \phi \) are arbitrary maps.

As in Remark 3.1 we formulate this in the language of Section 3.3. We set \( N \overset{\text{def}}{=} D \times \mathbb{N}^{d+1} \) and \( E \overset{\text{def}}{=} \phi \), so that \( V = T(D) \) with \( D = (N, E) \). We also give an inner product on \( \langle N \rangle \) by setting (using the same notational identifications as above),

\[
\langle \Xi, \Xi \rangle = \delta_{I} \delta_{k,k} k!.
\]

A tree \( \tau \in V \) is of the form

\[
\tau = \Xi_1 X^k \prod_{i=1}^{n} f_t(p_i)(\tau_i), \tag{3.5}
\]

with \( I \in D, k \in \mathbb{N}^{d+1}, n \geq 0, t_1, \ldots, t_n \in V, \phi = (t_1, p_1, \ldots, t_n, p_n) \in \phi \). We then set \( V^* \overset{\text{def}}{=} \mathbb{T}(D) \) and denote by \( \langle \cdot, \cdot \rangle \) the induced inner product on \( V^* \) as described in Section 3.3.
It is not hard to see that this inner product just keeps track of the symmetry factors analogous to that defined in (2.16). Extending the definition of $\bar{S}()$ in the natural way one has, for any $\tau, \bar{\tau} \in \mathcal{V}$, $\langle \tau, \bar{\tau} \rangle = \delta_{\tau, \bar{\tau}} \bar{S}(\tau)$.

Since $\mathcal{L}_- \cup \{0\}$ can be identified with a subset of $\mathcal{D}$ by identifying 0 with $\langle \emptyset, 0 \rangle$ and $\mathcal{I}$ with $\{l, 0\}$ where $\mathcal{I} = \{(l, 0)\} \in \mathcal{D}$, $\mathcal{F}$ can (and will) be identified with the corresponding subset of $\mathcal{V}$.

We also identify $\mathcal{T}^{ex}$ with a subset of $\mathcal{V}$ as follows. To a decorated tree $T_{t_0}^{m, \bar{m}}$ equipped with a type map $t : E_T \rightarrow \mathcal{L}$, we associate the decorated tree $\bar{T}_{t_0}^{m}$ where $\bar{T}$ is obtained from $T$ by removing all the edges with type in $\mathcal{L}_-$. (This is indeed again a tree since normal rules forbid to attach any further edge to an edge with a label in $\mathcal{L}_-$.) The decoration $m$ is given by $m = (m^e, m^x) = ((l, o), n)$ where for every $x \in N_T$, $l(x)$ is equal to $\{(t(e), e^f) : e \in E_x^-\}$ where $E_x^-$ are the edges incident to $x$ with type belonging to $\mathcal{L}_-$. The edge decoration $\bar{f}$ is defined by $\bar{f} = (t, e)$. For the rest of the paper, we use the notation $T_{t_0}^{m}$ and we revert to the notation $T_{t_0}^{m, \bar{m}}$ only when we need to rely on some results from [BHZ16], e.g. for the proofs given in Appendix A.3.

**Remark 3.3** Formally, the difference between $\mathcal{T}^{ex}$ and $\mathcal{V}$ is that $\mathcal{V}$ does not enforce the restrictions that trees should conform to the rule $R$ and that extended decorations should be compatible with edge types as dictated in [BHZ16] Def. 5.24: the only role played by $\mathcal{V}$ in the definition of $\mathcal{V}$ is through the definition of the label set $\mathcal{D}$.

We will often use the symbolic notation $[\mathcal{X}]$ as in [Hai14] Sec. 8 and [BHZ16] Sec. 4.3. In particular, the drivers $\Xi_t$, $t \in \mathcal{D}$ are given by (1.5). For $o \in \emptyset$, we also define an operator $\mathcal{J}_o : \mathcal{V} \rightarrow \mathcal{V}$ as suggested by (1.5): given $T_{t_0}^{m} \in \mathcal{V}$, $\mathcal{J}_o(T_{t_0}^{m})$ is the decorated tree obtained by adding a new root with node decoration equal to zero and joining this new root to the root of $T$ with an edge decorated by $o$.

**Remark 3.4** Note that as in [BHZ16] we do allow symbols of the form $\mathcal{J}_{(t, o)}[\mathcal{X}]$.

### 3.4 A class of allowable equations

Recall that in the theory of regularity structures one lifts a concrete fixed point problem to an abstract fixed point problem in a space of modelled distributions.

We define $\mathcal{Q}$ to consist of all tuples $(F^l_i)_{i \in \mathcal{I}}$ where $t$ ranges over $\mathcal{L}_+$, $\mathcal{I}$ ranges over $\mathcal{D}$, and for each such $t$ and $\mathcal{I}$ one has $F^l_i \in \mathcal{P}$. There is a restriction on the equations we can work with in that they must be compatible with the rule $R$ used to construct our regularity structure – we now describe a subset $\mathcal{Q} \subset \mathcal{Q}$ which enforces this constraint. First, define $\mathcal{N}_+ \subset \mathcal{N}$ to be collection of all node-types whose elements are all members of $\mathcal{L}_+ \times \mathbb{N}^{d+1}$. We then define a map $\hat{\mathcal{N}} : \mathcal{P} \rightarrow \mathcal{P}(\mathcal{N}_+)$ by setting, for $F$ given by (2.3),

$\hat{\mathcal{N}}(F) \equiv \bigcup_{1 \leq j \leq m} \{\alpha \sqcup \beta : \alpha \leq \alpha_j, \beta \in \hat{\mathcal{P}}(\mathcal{Q}(F_j))\}$. 

Definition 3.5 We say that \( F \in \mathcal{Q} \) obeys our fixed rule \( R \) if for every \( t \in \mathcal{L}_+ \), \((\tilde{l}, o) \in \mathcal{D} \), and \( N \in \hat{N}(F^l_{\tilde{l}, o}) \), one has \( o \in D(t, N \sqcup \tilde{l}) \). We denote by \( \mathcal{Q} \) the set of all \( F \in \mathcal{Q} \) which obey \( R \).

Remark 3.6 At first glance the definition above may seem to just enforce conditions on the labels \( o \), but recall that \( D(t, N) = \emptyset \) if \( N \not\in R(t) \), so that it implies in particular that \( \hat{N}(F^l_{\tilde{l}, o}) \subset R(t) \) for every \( l \in \mathcal{D} \) and \( t \in \mathcal{L}_+ \).

Up to now, we have not required any additional properties on our rule \( R \) beyond completeness and subcriticality with respect to \( \text{reg} \). We now introduce an additional non-degeneracy assumption.

Assumption 3.7 For every \( t \in \mathcal{L}_+ \), \( N \in R(t) \), and \( o \in \mathcal{O}_+ \), one has \( N \sqcup \{ o \} \in R(t) \).

Note that any subcritical rule \( R \) can be trivially extended to satisfy Assumption 3.7 while remaining subcritical with respect \( \text{reg} \), so this is really just a condition guaranteeing that we are considering a sufficiently large class of SPDEs. We give a simple equivalent definition of \( \mathcal{Q} \) under Assumption 3.7.

Proposition 3.8 Let \( F \in \mathcal{Q} \). Consider the following statements.

(i) \( F \in \mathcal{Q} \).

(ii) For all \( l = (\tilde{l}, o) \in \mathcal{D} \), \( t \in \mathcal{L}_+ \), and \( \alpha \in \mathbb{N}_0 \) such that \( o \not\in D(t, \alpha \sqcup \tilde{l}) \), one has \( D^\alpha F^l_t \equiv 0 \).

Then \( (i) \Rightarrow (ii) \) If Assumption 3.7 holds, then \( (i) \iff (ii) \).

Proof. \( (i) \Rightarrow (ii) \) Let \( F \in \mathcal{Q} \) and let \( l, t, \alpha \) be as in point \( (ii) \). Then necessarily \( o \not\in \hat{N}(F^l_{\tilde{l}, o}) \), from which it readily follows that \( D^\alpha F^l_t \equiv 0 \), which proves \( (ii) \).

For \( N \in \mathbb{N}_0 \), define \( N^- \overset{\text{def}}{=} N \mathbb{1}_{\text{reg}(t,p)<0} \in \mathbb{N}_0 \) (i.e., considering \( N \) as an element of \( N, N^- \) is obtained by removing all edge types \((t, p)\) for which \( \text{reg}(t, p) \geq 0 \)). Observe that under Assumption 3.7, it follows readily from the definition of \( D(t, N) \) that \( D(t, N^- \sqcup \tilde{l}) \subset D(t, N \sqcup \tilde{l}) \).

Suppose now that Assumption 3.7 holds. Let \( t \in \mathcal{L}_+ \), \( l = (\tilde{l}, o) \in \mathcal{D} \), and \( N \in \hat{N}(F^l_{\tilde{l}, o}) \). To prove \( (ii) \), it suffices to show that \( o \in D(t, N^- \sqcup \tilde{l}) \). Observe that the expansion \((\ref{eq:expansion})\) and definition of \( \hat{N}(F^l_{\tilde{l}, o}) \) implies that \( D^{N^-} F^l_{\tilde{l}, o} \) is not identically zero. If \( (ii) \) holds, then \( o \in D(t, N^- \sqcup \tilde{l}) \), and therefore \( (i) \) holds.

3.5 Truncations

In practice, one works with a truncated version of the space \( \mathcal{T}^{\text{ex}} \). We describe here the truncated spaces and projections used to define our fixed point map.

Definition 3.9 For \( \gamma \in \mathbb{R} \), let \( \mathcal{T}^{\text{ex}}_{\leq \gamma} \overset{\text{def}}{=} \{ \tau \in \mathcal{T}^{\text{ex}} : |\tau|_+ \leq \gamma \} \). Let \( \mathcal{T}^{\text{ex}}_{\leq \gamma} \leq \mathcal{T}^{\text{ex}} \) be the subspace spanned by \( \mathcal{T}^{\text{ex}}_{\leq \gamma} \), and define the projection \( Q_{\leq \gamma} : \mathcal{T}^{\text{ex}} \rightarrow \mathcal{T}^{\text{ex}}_{\leq \gamma} \) which acts as the identity on \( \tau \in \mathcal{T}^{\text{ex}} \) if \( \tau \in \mathcal{T}^{\text{ex}}_{\leq \gamma} \), and maps \( \tau \) to zero otherwise. We define \( \mathcal{T}^{\text{ex}}_{\leq \gamma} \), \( \mathcal{T}^{\text{ex}}_{\leq \gamma} \), and \( Q_{\leq \gamma} : \mathcal{T}^{\text{ex}} \rightarrow \mathcal{T}^{\text{ex}}_{\leq \gamma} \) similarly.
We further introduce a truncation map with the important property that it is additive with respect to tree multiplication (which does not hold for the $| \cdot |_+$-degree).

**Definition 3.10** For $\tau = T^m_1 \in \mathcal{T}^\text{ex}$ we call $L(\tau) \overset{\text{def}}{=} |E_T| + |m^x|$ the truncation parameter of $\tau$. For $L \in \mathbb{N}$, define

$$W_{\leq L} \overset{\text{def}}{=} \{ \tau \in \mathcal{T}^\text{ex} : L(\tau) \leq L \}.$$

Let $\mathcal{W}_{\leq L} \subset \mathcal{T}^\text{ex}$ be the subspace spanned by $W_{\leq L}$, and define the projection $p_{\leq L} : \mathcal{T}^\text{ex} \to \mathcal{W}_{\leq L}$ which acts as the identity on $\tau \in \mathcal{T}^\text{ex}$ if $\tau \in W_{\leq L}$, and maps $\tau$ to zero otherwise. We also set

$$\gamma_L \overset{\text{def}}{=} \max \{|\tau|_+ : \tau \in W_{\leq L}\},$$

and, for $\alpha \in \mathbb{R}$, set

$$L_\alpha \overset{\text{def}}{=} \max \{ L(\tau) : \tau \in \mathcal{T}^\text{ex}, |\tau|_+ \leq \alpha \}.$$

Note that $W_{\leq L}$ is a finite set for any $L \in \mathbb{N}$ and thus $0 \leq \gamma_L < \infty$. Note also that $L_\alpha \leq \bar{L} < \infty$ since, by subcriticality of the rule $R$, there are only finitely many $\tau \in \mathcal{T}^\text{ex}$ for which $|\tau|_+ \leq \alpha$. It holds that $L_\alpha$ is the smallest natural number for which $\tau \in W_{\leq L_\alpha}$ for all $\tau \in \mathcal{T}^\text{ex}$ such that $|\tau|_+ \leq \alpha$.

Note that $W_{\leq L}$ is closed under the action of $\mathcal{R}$ but not in general under the action of the structure group of $\mathcal{T}$. Finally, we will require the following definition when dealing with renormalised equations.

**Definition 3.11** For $L \in \mathbb{N}$, let

$$\bar{L} \overset{\text{def}}{=} \max \{ L(\tau) : \tau \in \mathcal{T}^\text{ex}, |\tau|_+ \leq \gamma_L \}.$$

Note that $L \leq \bar{L} < \infty$ and that for all $M \in \mathcal{R}$

$$M, M^* : \mathcal{T}^\text{ex}_{\leq \gamma_L} \to \mathcal{W}_{\leq L},$$

which follows from the fact that $M$ and $M^*$ preserve the $| \cdot |_+$-degree.

**Remark 3.12** In the remainder of the paper we will often continue working with the untruncated regularity structure $\mathcal{T}$ and then insert the needed projections into various expressions; these are easily converted to statements on an appropriately truncated regularity structure. We also remark that any statements we give involving continuity with respect to or convergence of models assume that one has truncated the regularity structure at some level.
3.6 Nonlinearities on trees

Let $\mathcal{T}^\text{ex} \overset{\text{def}}{=} \text{Span}\{X^p : p \in \mathbb{N}^{d+1}\}$ denote the sector of abstract Taylor polynomials in $\mathcal{T}^\text{ex}$. For every $t \in \mathcal{L}_+$ we define $\mathcal{T}^\text{ex}_t$, $\tilde{\mathcal{T}}^\text{ex}_t \subset \mathcal{T}^\text{ex}$ and $\overline{\mathcal{T}}^\text{ex}_t$, $\tilde{\overline{\mathcal{T}}}^\text{ex}_t \subset \mathcal{T}^\text{ex}$ via

$$
\mathcal{T}^\text{ex}_t \overset{\text{def}}{=} \{\tau \in \mathcal{T}^\text{ex} : \tau = J_{(t,0)}[\bar{\tau}] \text{ for some } \bar{\tau} \in \mathcal{T}^\text{ex}\}, \quad \mathcal{T}^\text{ex}_t \overset{\text{def}}{=} \mathcal{T}^\text{ex} \oplus \text{Span} \mathcal{T}^\text{ex}_t,
$$

$$
\overline{\mathcal{T}}^\text{ex}_t \overset{\text{def}}{=} \{\tau \in \mathcal{T}^\text{ex} : J_{(t,0)}[\bar{\tau}] \in \mathcal{T}^\text{ex}\}, \quad \tilde{\overline{\mathcal{T}}}^\text{ex}_t \overset{\text{def}}{=} \text{Span} \tilde{\overline{\mathcal{T}}}^\text{ex}_t.
$$

We note that one also has $\mathcal{T}^\text{ex} \subset \tilde{\overline{\mathcal{T}}}^\text{ex}_t$. The space $\mathcal{T}^\text{ex}_t$ contains all “jets” used to describe the left hand side of the $t$-component of our equation (25), while $\tilde{\mathcal{T}}^\text{ex}_t$ contains those used to describe its right hand side. Thanks to our assumptions on the underlying rule $R$, one has the following lemma, cf. [BHZ16, Eq. 5.11]. Note that we always refer to the $|\cdot|_+$-degree when speaking about the regularity of a sector.

**Lemma 3.13** For each $t \in \mathcal{L}_+$, $\mathcal{T}^\text{ex}_t$ and $\tilde{\mathcal{T}}^\text{ex}_t$ are sectors of $\mathcal{T}$ of respective regularities $\text{reg}(t) \wedge 0$ and $(\text{reg}(t) - |t|_+) \wedge 0$. \hfill $\square$

We also define $\mathcal{H}^\text{ex} \overset{\text{def}}{=} \bigoplus_{t \in \mathcal{L}_+} \mathcal{T}^\text{ex}_t$ and $\overline{\mathcal{H}}^\text{ex} \overset{\text{def}}{=} \bigoplus_{t \in \mathcal{L}_+} \tilde{\overline{\mathcal{T}}}^\text{ex}_t$.

For $p \in \mathbb{N}^{d+1}$ we write $\mathcal{D}^p$ for the abstract differential operator $\mathcal{D}^p : \mathcal{H}^\text{ex} \to \mathcal{T}^\text{ex}$ given by $J_{(t,0)}[\tau] \mapsto J_{(t,p)}[\tau]$, as well as $X^x \mapsto \frac{q!}{(q-p)!} X^{x-p}$ if $q \geq p$ and $X^x \mapsto 0$ otherwise. Given $U = (U_t)_{t \in \mathcal{L}_+} \in \mathcal{H}^\text{ex}$ we define $U = (U_{(t,p)})_{(t,p) \in \mathbb{E}} \in \bigoplus_{(t,p) \in \mathbb{E}} \mathcal{D}^p \mathcal{T}^\text{ex}_t$ by setting $U_{(t,p)} \overset{\text{def}}{=} \mathcal{D}^p U_t$.

Writing $\mathcal{M} \overset{\text{def}}{=} \bigoplus_{t \in \mathcal{L}_+} \mathcal{T}^\text{ex}_t$, we immediately obtain the following lemma from the implication (ii) $\Rightarrow$ (i) of Proposition 3.8.

**Lemma 3.14** Let $F \in \mathcal{Q}_{\Xi}$. Write $F_{\Xi} : \mathcal{M} \to \mathcal{M}$ for the map given by $U \mapsto (\sum_{t \in \mathcal{Q}_b} F_b^\dagger(U) \Xi_t) : b \in \mathcal{L}_+$ where

$$
F_b^\dagger(U) \overset{\text{def}}{=} \sum_{\alpha \in \mathbb{N}^\circ} \frac{D^\alpha F_b^\dagger(\langle U, 1 \rangle)}{\alpha!}(U - \langle U, 1 \rangle \mathbf{1})^\alpha,
$$

and, writing $U = (U_\alpha)_{\alpha \in \mathbb{E}}$, we set $\langle U, 1 \rangle \overset{\text{def}}{=} \langle \langle U_\alpha, 1 \rangle \rangle_{\alpha \in \mathbb{E}} \in \mathbb{R}^\mathbb{E}$. Then, for any $\gamma \in \mathbb{R}$, $\mathcal{Q}_{\leq \gamma} F_{\Xi}$ maps $\mathcal{H}^\text{ex}$ to $\mathcal{H}^\text{ex}$.

**Proof.** This follows from the fact that for $b \in \mathcal{L}_+$, $l \in \mathcal{Q}_b$, and any $\alpha \in \mathbb{N}^\circ$ with $D^\alpha F_b^\dagger \neq 0$, Proposition 3.8 guarantees that $(U - \langle U, 1 \rangle \mathbf{1})^\alpha \Xi_l \in \tilde{\overline{\mathcal{T}}}^\text{ex}_b$.

---

12A sector is a subspace of $\mathcal{T}^\text{ex}$ which is stable under the structure group and respects the decomposition into homogeneous subspaces, see [Hai14, Def. 2.5].
3.7 Coherence

For each $F \in \mathcal{Q}$ we define $\Upsilon^F : \mathcal{V} \to \mathcal{P}^\otimes$, $\Upsilon^F : \tau \mapsto \Upsilon^F[\tau] = (\Upsilon^F_t[\tau])_{t \in \mathcal{L}_1}$ by (2.10), the only difference being that we now allow to have $l \in \mathcal{D}$. Recall also that we identify $\mathcal{T}^{ex}$ with a subset of $\mathcal{V}$.

For $U \in \mathcal{H}^{ex}$ we define $U^R \in \mathcal{H}^{ex}$ by setting, for each $t \in \mathcal{L}_+$,

$$U^R_t = \sum_{\tau \in \mathcal{T}^{ex}_t} \frac{\langle U, \mathcal{I}_{(l,0)}[\tau] \rangle}{(\tau, \tau)}.$$ 

Additionally, we define a tuple $u^U \equiv (u^U_{l,p})$ where $u^U_{l,p} \in \mathcal{R}$ is given by setting $u^U_{l,p} \equiv \langle X^p, U \rangle = (1, U_{(l,p)})$. In this way, every $U \in \mathcal{H}^{ex}$ can be written uniquely as

$$U = \sum_{p \in \mathbb{N}^{d+1}} \frac{1}{p!} u^U_{l,p} X^p + \mathcal{I}_{(l,0)}[U^R] . \quad (3.8)$$

**Definition 3.15** We say that $U \in \mathcal{H}^{ex}$ is coherent to order $L \in \mathbb{N}$ with $F \in \mathcal{Q}$ if, for every $t \in \mathcal{L}_+$ and every $\tau$ such that $\mathcal{I}_{(l,0)}[\tau] \in \mathcal{W}_{L+1}$, one has

$$\langle U, \mathcal{I}_{(l,0)}[\tau] \rangle = \Upsilon^F_t[\tau](u^U).$$

We note the following equivalence.

**Lemma 3.16** Fix $F \in \mathcal{Q}$ and $L \in \mathbb{N}$. Consider $U \in \mathcal{H}^{ex}$ of the form (3.8). Then $U$ is coherent to order $L$ with $F$ if and only if, for every $t \in \mathcal{L}_+$,

$$p_{\leq L} \sum_{l \in \mathcal{D}_1} \mathcal{F}_t^l(U) \Xi_l = p_{\leq L} U^R_t .$$

**Proof.** This follows from Lemma 4.15 below, combined with the additivity of tree multiplication with respect to the truncation parameter $L(\tau)$. \hfill \Box

3.8 The main theorem

We define an action of $\mathcal{R}$ on $\mathcal{Q}$, written, for $M \in \mathcal{R}$, as $F \mapsto MF$ where $MF \in \mathcal{Q}$ is defined by setting, for each $t \in \mathcal{L}_+$ and $l \in \mathcal{D}_1$,

$$(MF)_l \equiv \Upsilon^F_t[M^* \Xi_l] = \sum_{\tau \in \mathcal{T}^{ex}_t} \frac{\langle M\tau, \Xi_l \rangle}{(\tau, \tau)} \Upsilon^F_t[\tau] \in \mathcal{P} . \quad (3.9)$$

We defer the proof of the following lemma to Appendix A.1

**Lemma 3.17** Let $F \in \mathcal{Q}$ and $M \in \mathcal{R}$. Under Assumption 2.7 it holds that $MF \in \mathcal{Q}$. 

The following lemma, whose proof is deferred to the very end of Section 5.7, implies that the map \( F \mapsto MF \) defines a (left) group action\(^{13}\) of \( \mathcal{R} \) on \( \mathcal{Q} \), which is not obvious from \( \ref{section:five} \).

**Lemma 3.18** Suppose Assumption (7.7) holds. Then for all \( F \in \mathcal{Q} \), \( M \in \mathcal{R} \), and \( \tau \in \mathcal{T}^{ex} \), it holds that \( \Upsilon F [M^* \tau] = \Upsilon MF [\tau] \).

For the rest of this section, we suppose that Assumption (7.7) is in place.

**Proposition 3.19** Fix \( F \in \mathcal{Q} \), \( L \in \mathbb{N} \), and \( M \in \mathcal{R} \). Suppose \( U \in \mathcal{H}^{ex} \) is coherent to order \( \bar{L} \) with \( F \), with \( \bar{L} \) as in Section 7.5. Then \( MU \) is coherent to order \( L \) with \( MF \).

**Proof.** One has, for every \( t \in \mathcal{L}_+ \), and \( J_{(t,0)}[\tau] \in W_{\leq L+1} \)

\[
\langle MU_t, J_{(t,0)}[\tau] \rangle = \langle U_t, M^* J_{(t,0)}[\tau] \rangle = \langle U_t, J_{(t,0)}[M^* \tau] \rangle = \Upsilon_t F [M^* \tau](u^L) = \Upsilon_t MF [\tau](u^{MU}) .
\]

Here the third equality uses the definition of coherence and that \( M^* \tau \in W_{\leq L} \) (which follows from (7.6)). The fourth equality uses Lemma 3.18 and that \( u^L = u^{MU} \). \( \square \)

Our main algebraic result can be stated as follows.

**Theorem 3.20** Let \( F \in \mathcal{Q} \), \( L \in \mathbb{N} \), and \( U \in \mathcal{H}^{ex} \) written as (3.8). Suppose that \( U \) satisfies, for every \( t \in \mathcal{L}_+ \),

\[
P_{\leq L} \sum_{l \in \mathcal{D}_1} F^l_t(U) \Xi_l = P_{\leq L}^{R}U^L .
\]

Then \( U \) is coherent to order \( \bar{L} \) with \( F \), and, for all \( M \in \mathcal{R} \) and \( t \in \mathcal{L}_+ \),

\[
P_{\leq L} MU_t^R = P_{\leq L} \sum_{l \in \mathcal{D}_1} (MF)_t^l(U) \Xi_l . \tag{3.10}
\]

**Proof.** Coherence of \( U \) to order \( \bar{L} \) with \( F \) follows from Lemma 3.16. It follows from Proposition 3.19 that \( MU \) is coherent to order \( L \) with \( MF \), from which we obtain (3.10) again by Lemma 3.16. \( \square \)

Note that the proof of Theorem 3.20 is a simple application of Lemma 3.16 and Proposition 3.19 which in turn rely on Lemmas 4.5 and 3.18 respectively. In Sections 4 and 5 we set up the combinatorial / algebraic framework which allows us to prove the latter two lemmas.

\(^{13}\)One also needs injectivity of the map \( F \mapsto (\Upsilon F)_t \) for every \( t \in \mathcal{L}_+ \), which is not obvious from Section 5.7.
4 Another space of labelled trees

4.1 The space $\mathcal{B}$

We apply the procedure in Section 3.3 to define another space of trees with a specified inner product. We keep $E$ as in Section 3.3 but introduce a new set of node decorations

$$N' \overset{\text{def}}{=} \left\{ \prod_{i=1}^{n} \mathcal{I}_{(t_i,p_i)}[X^{k_i}] : I \in \mathcal{D}, n \geq 0, (t_i, p_i) \in \emptyset, k_i \in \mathbb{N}^{d+1}, p_i < k_i \right\}.$$  

where the product over $[n]$ appearing above is treated as commutative. The inner product on $\langle N' \rangle$ is defined by

$$\left\langle \prod_{i=1}^{n} \mathcal{I}_{o_i}[X^{k_i}], \prod_{i=1}^{\tilde{n}} \mathcal{I}_{\tilde{o}_i}[X^{\tilde{k}_i}] \right\rangle \overset{\text{def}}{=} \delta_{\|i\|}\delta_{\|\tilde{n}\|} \sum_{i=1}^{n} \prod_{s \in S} \delta_{\tilde{o}_i,\tilde{o}(s)}\delta_{k_i,\tilde{k}(s)}(k_i - p_i)!.$$  

(4.1)

Setting $D' \overset{\text{def}}{=} (N', E)$, we then define the set $B \overset{\text{def}}{=} \mathcal{I}(D')$ and the inner product space $\mathcal{B} \overset{\text{def}}{=} \mathcal{I}(D')$ as prescribed in Section 3.3. In particular, it holds that every tree $\sigma \in \mathcal{B}$ can be uniquely written as

$$\sigma = Y \prod_{j \in J} \mathcal{J}_{o_j}[\sigma_j] = \Xi_I \left( \prod_{i \in I} \mathcal{I}_{o_i}[X^{k_i}] \right) \left( \prod_{j \in J} \mathcal{J}_{o_j}[\sigma_j] \right)$$  

(4.2)

where $I$ and $J$ are finite index sets, $I \in \mathcal{D}$, $o_i, o_j \in \emptyset$, $\sigma_j \in \mathcal{B}$, and $o_i = (t_i, p_i)$ with $p_i < k_i$ (and conversely, any such expression corresponds to a unique tree in $\mathcal{B}$).

Equivalently, $\mathcal{B}$ is the set of all decorated trees of the form $T^m_f$ where $m : N_T \rightarrow N$ and $f : E_T \rightarrow E$ are arbitrary maps.

For every $F \in \emptyset$ we define a linear map $\hat{\mathcal{Y}}_f^F[\cdot] : \mathcal{B} \rightarrow \mathcal{B}^{\mathbb{R}^+}$ as follows. For $\sigma \in \mathcal{B}$ of the form (4.2) and $t \in \mathcal{L}_+$, we define $\hat{\mathcal{Y}}_f^F[\sigma] \in \mathcal{B}$ inductively by setting

$$\hat{\mathcal{Y}}_f^F[\sigma] \overset{\text{def}}{=} \left( \prod_{i \in I} \mathcal{X}_{(t_i,k_i)} \right) \left( \prod_{j \in J} \hat{\mathcal{Y}}_f^F[\sigma_j] \right) \left[ \left( \prod_{i \in I \cup J} D_{o_i} \right) F^I \right]$$  

(4.3)

(the base case being implicitly defined with $J = \emptyset$).

Next we define a linear operator $Q : \langle N' \rangle \rightarrow \langle N \rangle$ as follows. Given $\sigma \in \mathcal{B}$ as in (4.2) we set

$$Q\sigma \overset{\text{def}}{=} \Xi_I \left( \prod_{i \in I} X^{k_i-p_i} \right)$$

We then have an extension $\mathcal{I}_{D',D}(Q)$ of $Q$ which is a linear map from $\mathcal{B}$ to $\mathcal{V}$. We will abuse notation and just write $Q$ instead of $\mathcal{I}_{D',D}(Q)$ for this extension, we will commit such an abuse of notation for other linear operators as well.

Remark 4.1 The intuition behind the set $\mathcal{B}$ is that its trees contain information about which components of the solution (and derivatives thereof) every polynomial term came from. In other words, a term $\mathcal{I}_{(t,p)}[X^{k_i}]$ at the root of a tree $\sigma \in \mathcal{B}$ indicates...
that the expansion of $Q U_i$ contributed a polynomial term $X^{k-p}$ to $\sigma$. Keeping track of this information facilitates several combinatorial proofs (particularly Lemma 4.5 below). The map $Q : B \to V$ simply discards this information.

**Lemma 4.2** Fix $F \in \mathcal{Q}$. It holds that $\hat{F}_i^F[\sigma] = 0$ for every $\sigma \in B$ and $t \in \mathfrak{L}_+$ for which $\mathcal{J}_{(t,0)}[Q\sigma] \in V \setminus T^\text{ex}$.

**Proof.** This follows from the implication (i) $\Rightarrow$ (ii) of Proposition 3.8 \qed

### 4.2 Coherent expansion on $\mathcal{V}$

We denote by $Q^* : \mathcal{V}^* \to \mathcal{B}^*$ the adjoint of $Q$, where $\mathcal{V}^*$ and $\mathcal{B}^*$ are the algebraic duals of $\mathcal{V}$ and $\mathcal{B}$ respectively (identified with the space of series in $V$ and $B$). Recall that $\mathcal{V}$ and $\mathcal{B}$ are equipped with an inner product, in particular we identify $\mathcal{V}^*$ as a subspace of $\mathcal{V}^*$. With our definitions we have the following lemma which is proved in Appendix [A.2]

**Lemma 4.3** For any $\tau \in \mathcal{V}$, $t \in \mathfrak{L}_+$, and $F \in \mathcal{Q}$, one has

$$\hat{F}_i^F[\tau] = \hat{F}_i^F[Q^* \tau]. \quad (4.4)$$

**Remark 4.4** While in principle $Q^* \tau \in \mathcal{B}^*$ is an infinite series, it is easy to see that $\hat{F}_i^F$ is non-zero for only finitely many of its terms. Hence $\hat{F}_i^F[Q^* \tau]$ is a well-defined element of $\mathcal{Q}$.

The following result is used in the proof of Lemma 3.16.

**Lemma 4.5** Let $F \in \mathcal{Q}$ and $U \in \mathcal{H}^\text{ex}$ written as (3.8). Then $U$ is coherent to all orders with $F$ if and only if for any $t \in \mathfrak{L}_+$,

$$\sum_{i \in \mathcal{D}_1} F_i^1(U) \Xi_i = U^R_t \quad (4.5)$$

**Proof.** Suppose $U$ is coherent to all orders with $F$. For any $t \in \mathfrak{L}_+$ and $\tau \in T^\text{ex}$ one can use Lemmas 4.2 and 4.3 along with the fact that $\langle U_t, \mathcal{J}_{(t,0)}[\tau] \rangle \neq 0$ only if $\mathcal{J}_{(t,0)}[\tau] \in T^\text{ex}$ to see that

$$\langle U_t, \mathcal{J}_{(t,0)}[\tau] \rangle = \hat{F}_i^F[\tau](u^U) = \hat{F}_i^F[Q^* \tau](u^U) = \sum_{\sigma \in \mathcal{B}} \hat{F}_i^F[\sigma](u^U) \frac{Q_{\sigma,\sigma}}{\langle \sigma, \sigma \rangle}.$$ 

Thus $U^R_t = \sum_{\sigma \in \mathcal{B}} \hat{F}_i^F[\sigma](u^U) \frac{Q_{\sigma,\sigma}}{\langle \sigma, \sigma \rangle}$ and, for each $(t, p) \in \mathcal{O}$, we can write

$$U_{(t,p)} = u_{(t,p)} \Xi_0 + \hat{U}_{(t,p)} + Q \hat{U}_{(t,p)}$$

where $\hat{U}_{(t,p)} \in \mathcal{T}$ and $\hat{U}_{(t,p)} \in \mathcal{B}$ are given by

$$\hat{U}_{(t,p)} \overset{\text{def}}{=} \sum_{q \in N^{t+1}} \frac{Q_{(t,p+q)}}{q!} X^q \quad \text{and} \quad \hat{U}_{(t,p)} \overset{\text{def}}{=} \sum_{\sigma \in \mathcal{B}} \hat{F}_i^F[\sigma] \frac{\mathcal{J}_{(t,p)}[\sigma]}{\langle \sigma, \sigma \rangle}.$$
We introduce some shorthand. First we set
\[ A \defeq (0 \times B) \sqcup (0 \times N^{d+1} \setminus \{0\}). \]
Second, for any \( \nu \in N^A \), we define \( \bar{\nu} \in N^0 \) by setting
\[ \bar{\nu}((b, p)) \defeq \sum_{\sigma \in B} \nu(((b, p), \sigma)) + \sum_{q \in N^{d+1} \setminus \{0\}} \nu(((b, p), q)). \]
Finally, for any \( \nu \in N^A \) with \( |\nu| < \infty \) we use the shorthand
\[
\begin{align*}
\nu^\nu & \defeq \prod_{(b, p) \in \emptyset, q \in N^{d+1} \setminus \{0\}} \left( \frac{(\bar{\nu}((b, p), q))}{q!} \right)^{\nu(((b, p), q))}, \\
(T^F)^\nu & \defeq \prod_{(b, p) \in \emptyset, \sigma \in B} \hat{T}^F_b \left[ \sigma \right]^{\nu(((b, p), \sigma))}, \\
\mathcal{J}^\nu & \defeq \prod_{(b, p) \in \emptyset, \sigma \in B} \left( \frac{\mathcal{J}((b, p), \sigma)}{\sigma, \sigma} \right)^{\nu(((b, p), \sigma))}, \\
\sigma(\nu) & \defeq \mathcal{J}^\nu \prod_{(b, p) \in \emptyset, q \in N^{d+1} \setminus \{0\}} \left( \mathcal{I}((b, p), X^{p+q}) \right)^{\nu(((b, p), q))}.
\end{align*}
\]
Now fix \( t \in \Sigma_+ \), then by Taylor expansion one has \( \sum_{i \in \mathcal{D}_t} F_i^t(U) \Xi_i \) is equal to
\[
\begin{align*}
\sum_{i \in \mathcal{D}_t} \frac{D^\eta F_i^t(U) \Xi_i}{\eta!} & \left[ \prod_{(b, p) \in \emptyset} \left( U_{(b, p)} + Q U_{(b, p)} \right)^{\eta(((b, p), \eta))} \right] \\
= \sum_{i \in \mathcal{D}_t} \frac{D^\eta F_i^t(U)}{\eta!} \sum_{\nu \in N^A} \frac{\eta!}{\nu!} \nu^\nu Q \left( \Xi_i (T^F)^\nu (U^U) \mathcal{J}^\nu \right) \\
= \sum_{i \in \mathcal{D}_t} \frac{D^\nu F_i^t(U)}{\nu!} \nu^\nu Q \left( \Xi_i (T^F)^\nu (U^U) \mathcal{J}^\nu \right) \\
= \sum_{i \in \mathcal{D}_t} \hat{T}^F_i \left[ \sigma^\nu \Xi_i (U^U) Q \right] \left( \sigma(\nu) \Xi_i \right) = \sum_{\sigma \in B} \hat{T}^F_i \left[ \sigma (U^U) Q \sigma \right] \left( \sigma(\nu) \Xi_i \right).
\end{align*}
\]
Above, in the sums over \( \nu \) and \( \eta \), we implicitly enforce that \( |\nu|, |\eta| < \infty \).

Conversely, suppose that (4.5) holds. Let \( V \in \mathcal{H}^{\text{ex}} \) be the unique element for which \( U^V = U^U \) and which is coherent to all orders with \( F \). It suffices to show that for \( t \in \Sigma_+ \) and every \( \tau \in \mathcal{T}^{\text{ex}} \) one has \( \langle V_t, J_t(\tau) \rangle = \langle U_t, J_t(\tau) \rangle \). We prove this by induction on the number of edges in \( \tau \). The base case when \( \tau \) has no edges follows from the definition of \( V \). Suppose now that \( \tau \) has \( k \geq 1 \) edges and that the claim is true for all \( b \in \Sigma_+ \) and all trees with at most \( k - 1 \) edges. Then
\[
\langle U_t, J_t(\tau) \rangle = \left( \sum_{i \in \mathcal{D}_t} F_i^t(U) \Xi_i, \tau \right) = \left( \sum_{i \in \mathcal{D}_t} F_i^t(V) \Xi_i, \tau \right) = \langle V_t, J_t(\tau) \rangle,
\]
where the first equality follows from (4.5), the second from the inductive hypothesis and the fact that the number of edges is additive with respect to tree multiplication, and the third from the coherence of \( V \) and the previous part. \qed
5 Grafting operators and action of the renormalisation group

We introduce grafting operators on our spaces of trees and show they possess several important properties. First, the maps \( \hat{\Upsilon}^F : \mathcal{B} \to \mathcal{P}L^+ \) and \( \Upsilon^F : \mathcal{B} \to \mathcal{P}L^+ \) become (pre-Lie) morphisms with respect to these operators (Lemma 5.1 and Corollary 5.2). Second, they are in suitable “co-interaction” with the renormalisation group \( R \) (Proposition 5.3). Third, they allow us to decompose the construction of trees into elementary grafting operations starting from a simple set of generators (Proposition 5.4). Together, these facts lead to the proof of Lemma 5.5.

5.1 Grafting operators on \( \mathcal{B} \)

Definition 5.1

(i) For \( o \in \mathcal{O} \), let \( \sim_o : \mathcal{B} \otimes \mathcal{B} \to \mathcal{B} \) be the linear map which, for all \( \sigma, \bar{\sigma} \in \mathcal{B} \) with \( \sigma \) of the form (4.2), is given inductively by

\[
\sigma \sim_o \bar{\sigma} \overset{\text{def}}{=} \sigma \sim_o \text{root} + \sigma \sim_o \text{non-root} + \sigma \sim_o \text{poly} \bar{\sigma} \tag{5.1}
\]

(ii) For \( l = 0, \ldots, d \), define \( \uparrow_l : \mathcal{B} \to \mathcal{B}^* \) for \( \sigma \in \mathcal{B} \) of the form (4.2) inductively by

\[
\uparrow_l \sigma \overset{\text{def}}{=} \Xi \sum_{i \in I} \mathcal{T}_{o_i} [X^{k_i + l_i}] \prod_{i \in I \setminus \{i\}} \mathcal{T}_{o_j} [X^{k_j}] \prod_{j \in J} \mathcal{F}_{o_j} [\sigma_j] \tag{5.2}
\]

The motivation for this definition comes from the following lemma. For \( o \in \mathcal{O} \), let \( \partial_o : \mathcal{P}L^+ \times \mathcal{P}L^+ \to \mathcal{P}L^+ \) be the bilinear map given by setting, for any \( b \in \mathbb{L}_+ \) and \( F, \hat{F} \in \mathcal{P}L^+ \), \( (F \circ_o \hat{F})_b \overset{\text{def}}{=} F_1 \cdot D_o F_0 \).

Lemma 5.2

Let \( F \in \mathcal{O} \), \( o \in \mathcal{O} \), \( l \in \{0, \ldots, d\} \), and \( \sigma, \bar{\sigma} \in \mathcal{B} \). It holds that

\[
\hat{\Upsilon}^F [\sigma \sim_o \bar{\sigma}] = \hat{\Upsilon}^F [\bar{\sigma}] \circ_o \hat{\Upsilon}^F [\sigma] \tag{5.3}
\]

and

\[
\hat{\Upsilon}^F [\uparrow_l \sigma] = \partial_l \hat{\Upsilon}^F [\sigma] \tag{5.4}
\]

Remark 5.3

Although \( \uparrow_l \sigma \) is a series in \( \mathcal{B} \), note that \( \hat{\Upsilon}^F \) vanishes on all but a finite number of its terms, hence the LHS of (5.4) is well-defined as an element of \( \mathcal{P}L^+ \).
Proof. From the definition (4.3) and the Leibniz rule, we see that $\tilde{T}^F[\tilde{\sigma}] \cdot_o \tilde{T}^F[\sigma]$ splits into a sum of three terms. We immediately see that $\tilde{T}^F[\tilde{\sigma} \wedge^\text{root}_o \sigma]$ and $\tilde{T}^F[\tilde{\sigma} \wedge^\text{poly}_o \sigma]$ from the expression (5.3) match two of the terms from the Leibniz rule. The term in $\tilde{T}^F[\tilde{\sigma} \wedge^\text{non-root}_o \sigma]$ then matches the final term from the Leibniz rule by an induction on the number of edges in $\sigma$, which completes the proof of (5.3).

The proof of (5.4) follows in an identical manner. \qed

We now provide an expression for the adjoint of $\wedge^*_o$ and $\uparrow_l$. For a tree $\sigma = T^m_i \in \mathcal{B}$ and an edge $(x, y) = e \in E_T$, let $P^e \sigma \in \mathcal{B}$ be the subtree of $\sigma$ with node set $N_{P^e \sigma} \overset{\text{def}}{=} \{ z \in N_T : z \geq y \}$, and for which the corresponding decoration maps are given by restrictions of $m$ and $f$. Let $R^e \sigma$ be the subtree of $\sigma$ with node set $N_{R^e \sigma} \overset{\text{def}}{=} N_T \setminus N_{P^e \sigma}$ and decoration map again given by restrictions of $m$ and $f$. We call $P^e \sigma$ and $R^e \sigma$ the branch and trunk respectively of a cut at $e$. Also, for $(t, k) \in B$ and $p \geq k$, we define $R^e_{(t, k), p} \sigma := R^e \sigma$ if $p = k$, and otherwise define $R^e_{(t, k), p} \sigma \in \mathcal{B}$ as the tree obtained from $R^e \sigma$ by adding $J_{(t, k)}[X^p]$ to the node decoration at $x$.

Lemma 5.4 (i) For $o = (t, p) \in \emptyset$, consider the map $\wedge^*_o : \mathcal{B} \to \mathcal{B} \otimes \mathcal{B}$ given for any $\sigma = T^m_i \in \mathcal{B}$ by

$$\wedge^*_o \sigma \overset{\text{def}}{=} \sum_{0 \leq k \leq p} \sum_{e \in E_T} \delta_{(e, (t, k))} (p - k)! P^e \sigma \otimes R^e_{(t, k), p} \sigma. \quad (5.5)$$

Then for all $\sigma_1, \sigma_2, \sigma \in \mathcal{B}$

$$\langle \sigma_1 \otimes \sigma_2, \wedge^*_o \sigma \rangle = \langle \sigma_1 \wedge^*_o \sigma_2, \sigma \rangle. \quad (5.6)$$

(ii) For $l = 0, \ldots, d$, define $\uparrow^*_l : \mathcal{B} \to \mathcal{B}$ for all $\sigma = T^m_i \in \mathcal{B}$ by

$$\uparrow^*_l \sigma \overset{\text{def}}{=} \sum_{x \in N_T} \sum_{\{k_i \mid l - p_i l \} \tilde{\sigma}} (k_i l - p_i l) \tilde{\sigma}, \quad (5.7)$$

where in the final sum we denoted $m(x) = \prod_{i \in I} \mathcal{I}_{(y, p_i)}[X^{k_i}]$ and $\tilde{\sigma} \overset{\text{def}}{=} T^m_i \in \mathcal{B}$ with $\tilde{m}(y) = m(y)$ for all $y \in N_T \setminus \{ x \}$ and

$$\tilde{m}(x) = \begin{cases} \prod_{i \in I} \mathcal{I}_{(y, p_i)}[X^{k_i - e_i}] \prod_{i \in I \setminus \{ i \}} \mathcal{I}_{(y, p_i)}[X^{k_i}] & \text{if } k_i - e_i > p_i, \\ \prod_{i \in I \setminus \{ i \}} \mathcal{I}_{(y, p_i)}[X^{k_i}] & \text{if } k_i - e_i = p_i. \end{cases}$$

Then $\langle \tilde{\sigma}, \uparrow^*_l \sigma \rangle = \langle \uparrow_l \sigma, \sigma \rangle$ for all $\sigma, \tilde{\sigma} \in \mathcal{B}$.

Proof. (i) For $\sigma$ given by (4.2), note that $\wedge^*_o$ admits the inductive form

$$\wedge^*_o \sigma = \wedge^*_o \sigma \wedge^* \sigma + \wedge^*_o \sigma \wedge^* \sigma$$
where the RHS is understood as an element of $\mathcal{F}_o$. We used an abuse of notation by assuming that $\mathcal{F}_o \to \mathcal{F}_o$ whose adjoint follows from the definition of the inner product that $\langle \sigma_1 \otimes \sigma_2, \mathcal{F}_o \rangle$ is given by the terms in $\langle \sigma_1 \otimes \sigma_2, \mathcal{F}_o \otimes \mathcal{F}_o \rangle$ with $p = k$ and $p < k$ respectively. It now follows by an induction on the number of edges in $\sigma$ that $\langle \sigma_1 \otimes \sigma_2, \mathcal{F}_o \rangle = \langle \sigma_1 \otimes \sigma_2, \mathcal{F}_o \rangle$, which completes the proof of (5,6). Point (ii) follows by identical considerations by noting that $\mathcal{T}_j$ admits the inductive form

$$\mathcal{T}_j = \Xi \sum_{k \in I} (k_1[l] - p(t)) \mathcal{T}_{(t, p, t)} \otimes X^{k_1 - \epsilon_l} \prod_{i \in I \setminus \{t\}} \mathcal{T}_{(t, p, t)} \prod_{j \in J} \mathcal{F}_{o_j}(\sigma_j)$$

where we used an abuse of notation by assuming that $\mathcal{T}_{(t, p, t)} \otimes X^{k_1 - \epsilon_l}$ if missing in the first sum in the case that $k_1 - \epsilon_l = p(t)$.

5.2 Grafting operators on $\mathcal{Y}$

For a tree $\tau = T_l^m \in \mathcal{Y}$ and an edge $(x, y) = e \in E_T$, we define the branch and trunk $P^e \tau, R^e \tau \in \mathcal{Y}$ of a cut at $e$ in the identical manner as for $\mathcal{B}$. For a node $x \in N_T$ and $q \in \mathbb{N}^{d+1}$, let $m^\pm_q : N_T \to \mathcal{O} \times \mathbb{Z}^{d+1}$ be defined by

$$m^\pm_q(y) = \begin{cases} (m^\pm(x), m^X(x) \pm q) & \text{if } x = y, \\ m(y) & \text{otherwise}. \end{cases}$$

$m^\pm_q$ agrees with $m$ at every node of $T$ except $x$ and increases / decreases by $q$ the second component of $m(x)$ at $x$. We extend the notation to

$$\tau^\pm_q = \mathbb{1}\{m^X(x) \pm q \geq 0\}(T, m^\pm_q, \tau),$$

where the RHS is understood as an element of $\mathcal{Y}$.

We now describe a family of grafting operators $\mathcal{G}(T_l^m) : \mathcal{Y} \otimes \mathcal{Y} \to \mathcal{Y}$ for which it holds that $Q^* \mathcal{G}(T_l^m) = \mathcal{G}(T_l^m) (Q^* \otimes Q^*)$. We prefer to define $\mathcal{G}(T_l^m)$ in terms of its adjoint.

**Definition 5.5** For $(t, p) \in \emptyset$, let $\mathcal{G}(T_l^m) : \mathcal{Y} \otimes \mathcal{Y} \to \mathcal{Y}$ be the unique linear map whose adjoint $\mathcal{G}(T_l^m)^* : \mathcal{Y} \to \mathcal{Y} \otimes \mathcal{Y}$ is given for all $\tau = T_l^m \in \mathcal{Y}$ by

$$\mathcal{G}(T_l^m)^* \tau = \sum_{0 \leq k \leq p(x, y) \in E_T} \sum \frac{\mathbb{1}\{x, y\}(t, k)}{(p - k)!} P^k(x, y) \mathcal{F}_{o(x, y)}(\tau) \otimes [P^0(x, y) - 1]^{p-k}.$$  \hfill (5.8)
In words, the factor in the right tensor of the summands appearing on the RHS of (5.8) is obtained from $\tau$ by removing the branch $F_{(t,k)}[P(x,y)\tau]$ and adding $X^{p-k}$ to the decoration at $x$ (adding nothing if $k = p$). We give a pictorial example below in which $p \geq k$ and where we have explicitly labelled two edges and two nodes.

\[
\hat{\wedge}(t,p) \equiv X^p \ast \bigg[ \frac{1}{(p-k)!} \bigg[ \Xi \bigg[ \prod_{j \in \mathcal{I}_o} \tau_j \bigg] \bigg] \bigg] = \Xi X^{p-k} + \Xi X^p \ast \Xi X^{p-k} + \cdots.
\]

**Remark 5.6** For $(t, p) \in \mathcal{O}$, one is able to give a precise definition of the grafting operator $\hat{\wedge}(t,p)$ similar to (5.7). Indeed, for $\tau \in \mathcal{V}$ and $\bar{\tau} = \Xi X^k \bigg( \prod_{j \in \mathcal{I}_o} \tau_j \bigg)$, we have

\[
\tau \hat{\wedge}(t,p) \bar{\tau} = \sum_{\ell} \left( \begin{array}{c} k \\ \ell \end{array} \right) \Xi X^{k-\ell} F_{(t,p-\ell)}[\tau] \bigg( \prod_{j \in \mathcal{I}_o} \tau_j \bigg) + \Xi X^k \bigg( \prod_{j \in \mathcal{I}_o} \tau_j \hat{\wedge}(t,p) \tau_j \bigg).
\]

**Definition 5.7** For $i \in \{0, \ldots, d\}$, let $\hat{\uparrow}_i : \mathcal{V} \to \mathcal{V}$ be the unique linear map with adjoint given for all $\tau = T^m \in \mathcal{V}$ by

\[
\hat{\uparrow}_i^* \tau \overset{\text{def}}{=} \sum_{x \in N_T} m^x(i)[x] \tau - e_i,
\]

where we write $m(x) = (m^x(0), (m^x(0)[0], \ldots, m^x(0)[d])) \in \mathcal{D} \times \mathbb{N}^{d+1}$.

We give a pictorial example for the above definition with one node explicitly labelled.
Note that $\land_\circ$ and $\uparrow_1$ extend to well-defined maps $\mathcal{B}^* \otimes \mathcal{B}^* \to \mathcal{B}^*$ and $\mathcal{B}^* \to \mathcal{B}^*$ respectively (this can be seen from Lemma 5.7 or directly from the triangular structure of the maps).

**Lemma 5.8** Let $(t, p) \in \emptyset$ and $l \in \{0, \ldots, d\}$. Then, as maps from $\mathcal{V} \otimes \mathcal{V}$ to $\mathcal{B}^*$,

$$Q^* \land_{(t,p)} = \land_{(t,p)} (Q^* \otimes Q^*)$$

and, as maps from $\mathcal{V} \to \mathcal{B}^*$,

$$\uparrow_1 Q^* = Q^* \uparrow_1.$$  

**Proof.** Considering the dual statements, it suffices to show that for all $\sigma \in \mathcal{B}$,

$$\land_{(t,p)}(Q\sigma) = (Q \otimes Q) \land_{(t,p)} \sigma,$$

and

$$\uparrow_1^T(Q\sigma) = Q(\uparrow_1^T \sigma).$$

To show (5.12), observe that, by definition of $Q$, there is a bijection between the edges with decoration $(t, k)$ in $Q\sigma$ and edges with decoration $(t, k)$ in $\sigma$. Furthermore, for every cut appearing in the sum (5.5) of Lemma 5.7 with corresponding term $\frac{1}{(p-k)!} h \otimes t$, it holds that $\frac{1}{(p-k)!} (Qh) \otimes (Qt)$ is the term appearing from the corresponding cut in (5.8), from which (5.12) follows.

To show (5.13), consider a node $x$ in $\sigma$ with decoration $\bar{x} \in \mathcal{B}$. Denote by $\bar{x}$ the corresponding node in $Q\sigma$. Note that the polynomial decoration at $\bar{x}$ is $k \overset{x}{=} \sum_{l \in f} (k_l - p_l)$. Every term $\tilde{\sigma}$ of $\uparrow_1^\tau \sigma$ in the sum (5.7) then corresponds to a term in $Q\tilde{\sigma}$, up to a combinatorial factor, obtained by lowering the polynomial decoration at $\bar{x}$ by $\epsilon_l$. It remains to verify that the correct combinatorial factor is obtained. To this end, the contribution from $x$ to the factor in front of $\uparrow_1^T Q\sigma$ is $k[l]$. On the other hand, if $\mathcal{I}_{(k,p)}[X^{k_l}]$ at $x$ was lowered first by $\epsilon_l$ from $\uparrow_1^T$, and then $Q$ was applied, its contribution to the combinatorial factor becomes $k_l[l] - p_l[l]$ (provided $k_l - p_l \geq \epsilon_l$). Running over all polynomial decorations at $x$ gives the total combinatorial factor of $\sum_{l \in f} (k_l[l] - p_l[l]) = k[l]$ as desired. \hfill \Box

**Corollary 5.9** For all $F \in \hat{\mathcal{Q}}$, $o \in \emptyset$, and $\tau, \bar{\tau} \in \mathcal{V}$,

$$\Upsilon^F[\tau \land_\circ \bar{\tau}] = \Upsilon^F[\tau] \land_0 \Upsilon^F[\bar{\tau}].$$

Furthermore, for all $i = 0, \ldots, d$,

$$\partial_i \Upsilon^F[\tau] = \Upsilon^F[\uparrow_1 \tau].$$

**Proof.** To prove (5.14), observe that, by Lemmas 4.3 and 5.2,

$$\Upsilon^F[\tau] \land_0 \Upsilon^F[\bar{\tau}] = \Upsilon^F[Q^* \tau] \land_0 \Upsilon^F[Q^* \bar{\tau}] = \Upsilon^F[Q^* \tau \land_\circ (Q^* \bar{\tau})]$$

$$= \Upsilon^F[Q^* (\tau \land_\circ \bar{\tau})] = \Upsilon^F[\tau \land_\circ \bar{\tau}],$$

where the third equality follows from (5.10). The proof of (5.15) follows in the same manner using now (5.11). \hfill \Box
5.3 Interaction with the renormalisation group

An important property of the grafting operators \( \hat{\land}_{o} \) is that its adjoint suitably preserves \( \mathcal{T}^{ex} \subset \mathcal{V} \).

**Lemma 5.10** For all \( o \in \emptyset \) and \( i \in \{0, \ldots, d\} \), it holds that \( \hat{\land}_{o}^{*} \) (resp. \( \hat{\land}_{i} \)) maps \( \mathcal{T}^{ex} \) to \( \mathcal{T}^{ex} \otimes \mathcal{T}^{ex} \) (resp. \( \mathcal{T}^{ex} \)).

**Proof.** The claim that \( \hat{\land}_{i} \) maps \( \mathcal{T}^{ex} \) to \( \mathcal{T}^{ex} \) is obvious. For \( \hat{\land}_{o}^{*} \), observe that normality of the rule \( R \) and the explicit description of the set of trees \( \mathcal{T}^{ex} \) \cite{BH16} Lem. 5.25] imply that \( P^{e}_{\tau} \otimes R^{e}_{\tau} \in \mathcal{T}^{ex} \) for any \( \tau \in \mathcal{T}^{ex} \) and \( e \in E_{\tau} \). The conclusion follows from the expression (5.8) for \( \hat{\land}_{o}^{*} \).

Define the linear map \( \hat{\land}_{o} : \mathcal{T}^{ex} \otimes \mathcal{T}^{ex} \to \mathcal{T}^{ex} \) given by \( \tau \hat{\land}_{o} \tau' = \pi_{\mathcal{T}^{ex}}(\tau \hat{\land}_{o} \tau') \), where \( \pi_{\mathcal{T}^{ex}} : \mathcal{V} \to \mathcal{T}^{ex} \) is the canonical projection. The following is a consequence of Lemma 5.10.

**Corollary 5.11** It holds that \( \hat{\land}_{o} \) is the adjoint of \( \hat{\land}_{o}^{*} : \mathcal{T}^{ex} \to \mathcal{T}^{ex} \otimes \mathcal{T}^{ex} \).

The following proposition is proved in Appendix A.3.

**Proposition 5.12** Let \( M \in \mathfrak{H} \). Then

1. For \( i = 0, \ldots, d \), it holds on \( \mathcal{T}^{ex} \) that
   \[
   M^{*} \hat{\land}_{i} = \hat{\land}_{i} M^{*}.
   \]  (5.16)

2. For all \( \tau, \tau' \in \mathcal{T}^{ex} \) and \( o \in \emptyset \)
   \[
   (M^{*} \tau) \hat{\land}_{o} (M^{*} \tau') = M^{*} (\tau \land_{o} \tau').
   \]  (5.17)

**Corollary 5.13** Let \( M \in \mathfrak{H} \). Then for any \( t \in \mathcal{L}_{+}, l \in \mathcal{D}, k \in \mathbb{N}^{d+1} \):

\[
\mathcal{T}^{MF}_{t} [\Xi_{l} X^{k}] = \mathcal{T}^{F}_{t} [M^{*} (\Xi_{l} X^{k})].
\]  (5.18)

**Proof.** For any \( t \in \mathcal{L}_{+}, l \in \mathcal{D}, k \in \mathbb{N}^{d+1} \),

\[
\mathcal{T}^{MF}_{t} [\Xi_{l} X^{k}] = \partial^{k} \mathcal{T}^{MF}_{t} [\Xi_{l}] = \partial^{k} \mathcal{T}^{F}_{t} [M^{*} \Xi_{l}] = \mathcal{T}^{F}_{t} [M^{*} (\Xi_{l} X^{k})],
\]

where we have used (5.15), the identity \( (\hat{\land})^{k} \Xi_{l} = \Xi_{l} X^{k} \) (where \( (\hat{\land})^{k} = \prod_{i=0}^{d} (\hat{\land}_{i})^{k[i]} \)), which is well defined due to the commutativity of \( \hat{\land}_{i} \) and \( \hat{\land}_{j} \), and (5.16) which implies \( M^{*} (\hat{\land})^{k} = (\hat{\land})^{k} M^{*} \).

Let us write \( \mathfrak{D} \subset \mathcal{T}^{ex} \) for the set of all elements of the form \( \Xi_{l} X^{k} \) with \( k \in \mathbb{N}^{d+1} \) and \( l \in \mathcal{D} \). We then have the following universal property of the space \( \mathcal{V} \) with the grafting operators \( (\hat{\land}_{o})_{o \in \emptyset} \), the proof of which will be given in Appendix A.4.
Proposition 5.14 The space $\mathcal{V}$ is freely generated by the family ($\triangleleft_o$)$_{o \in \mathfrak{g}}$ with generators $\hat{\mathfrak{D}}$. More precisely, consider any vector space $V$ equipped with bilinear operators ($\triangleleft_o$)$_{o \in A}$. $\triangleleft_o : V \times V \rightarrow V$, which satisfy the pre-Lie identity for all $\alpha, \tilde{\alpha} \in A$ and $x, y, z \in V$,

$$(x \triangleleft_o y) \triangleleft_o z - x \triangleleft_o (y \triangleleft_o z) = (y \triangleleft_o x) \triangleleft_o z - y \triangleleft_o (x \triangleleft_o z).$$

Then for any map $\Phi : \hat{\mathfrak{D}} \rightarrow V$ and $\Psi : \mathfrak{g} \rightarrow A$, there exists a unique extension of $\Phi$ to a linear map $\hat{\Phi} : \mathcal{V} \rightarrow V$ which satisfies for all $o \in \mathfrak{g}$ and $\tau, \tilde{\tau} \in \mathcal{V}$

$$\hat{\Phi}(\tau \triangleleft_o \tilde{\tau}) = (\hat{\Phi}\tau) \triangleleft_{\Psi(o)} (\hat{\Phi}\tilde{\tau}).$$

Remark 5.15 In what follows, we will only use the fact that $\mathcal{V}$ is generated by $\hat{\mathfrak{D}}$ and $(\triangleleft_o)_{o \in \mathfrak{g}}$; we emphasize that this generation is free only to highlight the algebraic structure of $\mathcal{V}$.

Corollary 5.16 $\mathcal{V}^{ex}$ is generated by the family $(\triangleleft_o)_{o \in \mathfrak{g}}$ with generators $\hat{\mathfrak{D}}$.

Proof of Lemma 3.18 By Proposition 5.14, identity (5.18), $\tau^F \circ M^* \circ \text{MF}$ agree on $\mathfrak{D}$. Since $MF \in \mathfrak{g}$ by Lemma 3.17, observe that Proposition 3.8 implies that $\tau^{MF}[\tau] = 0$ for all $\tau \in \mathcal{V} \setminus \mathcal{V}^{ex}$, and thus $\tau^{MF} \circ \pi_{\mathcal{V}^{ex}} = \tau^{MF}$. Therefore, applying (5.14) to $\tau^{MF}$, we see that for all $\tau, \tilde{\tau} \in \mathcal{V}^{ex}$ and $o \in \mathfrak{g}$

$$\tau^{MF}[\tau \triangleleft_o \tilde{\tau}] = \tau^{MF}[\tau] \triangleleft_{o} \tau^{MF}[\tilde{\tau}].$$

On the other hand, by (5.17), we have

$$\tau^{F}[M^*(\tau \triangleleft_o \tilde{\tau})] = \left(\tau^{F}[M^*\tau]\right) \triangleleft_{o} \left(\tau^{F}[M^*\tilde{\tau}]\right).$$

It thus follows from Corollary 5.16 that $\tau^{MF} = \tau^{F} \circ M^*$ as desired.

6 Analytic theory and a generalised Da Prato–Debussche trick

6.1 Admissible models

For each $t \in \mathfrak{L}_+$ we fix a decomposition $G_t = K_t + R_t$ on $\Lambda \setminus \{0\}$ where

- $K_t(x)$ is supported in the ball $|x|_{\sigma} \leq 1$ and coincides with $G_t(x)$ whenever $|x|_{\sigma} \leq 1/2$.
- For a parameter $\gamma \in \mathbb{R}$ to be defined later, and for every polynomial $Q$ on $\Lambda$ of $s$-degree less than $\gamma + |t|_{\sigma}$, one has

$$\int_{\Lambda} K_t(z)Q(z) \, dz = 0.$$

- One has $K_t(t, x) = R_t(t, x) = 0$ whenever $t < 0$.
- $R_t : \Lambda \rightarrow \mathbb{R}$ is a smooth function and satisfies, for every $k \in \mathbb{N}^{d+1}$, the bound

$$\sup_{t \geq 0} \sup_{x \in \mathbb{T}^d} e^{\chi t}|(D^k R_t)(t, x)| < \infty$$

for some $\chi > 0$. 

We write $K$ for the tuple $(K_t)_{t \in \mathbb{R}_+}$. We also write $\Omega_\infty$ for the set of all tuples $\xi = (\xi_t)_{t \in \mathbb{R}}$ where for each $t \in \mathbb{R}_+$, $\xi_t : \Lambda \to \mathbb{R}$ is a smooth function. For $\xi \in \Omega_\infty$, we denote by $Z^\xi$ the model on $\mathcal{H}$ given by the canonical $K$-admissible lift of $\xi$. We write $\mathcal{M}_\infty$ for the space of all smooth $K$-admissible models on $\mathcal{H}$.

We introduce a family of pseudo-metrics on $\mathcal{M}_\infty$ indexed by compact $\mathcal{R} \subset \mathbb{R}^{d+1}$ and $\ell \in A = \{|\tau|_+ : \tau \in T^\infty\}$. Given $(\Pi, \Gamma)$ and $(\bar{\Pi}, \bar{\Gamma})$ one sets $\mathcal{M}_\infty$,

$$
\|(\Pi, \Gamma); (\bar{\Pi}, \bar{\Gamma})\|_{\mathcal{R}, \ell} \defeq \|\Pi - \bar{\Pi}\|_{\mathcal{R}, \ell} + \|\Gamma - \bar{\Gamma}\|_{\mathcal{R}, \ell},
$$

where

$$
\|\Pi - \bar{\Pi}\|_{\mathcal{R}, \ell} \defeq \sup \left\{ \left| \frac{(\Pi_z - \bar{\Pi}_z)\tau, S^A_{\lambda}\varphi}{\lambda^\ell} \right| : x \in \mathcal{R}, \tau \in T^\infty, \lambda \in (0, 1], \varphi \in B_{x, \tau} \right\},
$$

$$
\|\Gamma - \bar{\Gamma}\|_{\mathcal{R}, \ell} \defeq \sup \left\{ \frac{\|\Gamma_{xy}\tau - \bar{\Gamma}_{xy}\tau\|}{\|x - y\|^{m-\ell}} : x, y \in \mathcal{R}, x \neq y, \tau \in T^\infty, m \in [r, \ell] \cap A \right\}.
$$

Above, we have used the notation $T^\infty_{\ell} \defeq \{ \tau \in T^\infty : |\tau|_+ = \ell \}$, for $a \in T^\infty$ of the form $a = \sum_{\tau \in T^\infty} a_\tau \tau$ and $m \in A$ we set $\|a\|_m \defeq \sup\{|a_\tau| : \tau \in T^\infty_m\}$, and we set $r \defeq 1 - \min A$. Note that for any fixed $\gamma \geq 0$, the family of pseudo-metrics

$$
\left\{ \|\cdot : \cdot\|_{\mathcal{R}, \ell} : \ell \in A \cap (-\infty, \gamma], \mathcal{R} \subset \mathbb{R}^{d+1} \text{ compact} \right\}
$$

generates a metric $d_\gamma$ on $\mathcal{M}_\infty$. Denote by $\mathcal{M}_0$ the completion\footnote{The completion does not depend on the choice of $\gamma \geq 0$. This is a consequence of the fact that admissible models are completely determined (in a continuous way) once one knows their restriction to symbols $\tau$ with $|\tau|_+ \leq 0$.} of $\mathcal{M}_\infty$ under $d_\gamma$.

To prepare for Proposition 6.18 we define a stronger metric on a subset of $\mathcal{M}_0$.

**Definition 6.1** Given $Z, \tilde{Z} \in \mathcal{M}_0$ we define

$$
\|Z; \tilde{Z}\| \defeq \frac{1}{n^2 + 1} \|Z; \tilde{Z}\|_{\mathcal{R}_n},
$$

where

$$
\mathcal{R}_n \defeq [n - 1, n + 1] \times T^d \subset \Lambda,
$$

and for any compact $\mathcal{R} \subset \Lambda$, $\|Z; \tilde{Z}\|_{\mathcal{R}} \defeq \max_{\ell \leq 0} \|Z; \tilde{Z}\|_{\mathcal{R}, \ell}$. We define $\|Z\|_{\mathcal{R}} = \|Z; 0\|_{\mathcal{R}}$ and $\|Z\| = \|Z; 0\|$ analogously by removing the presence of $\Pi$ and $\bar{\Gamma}$ in (6.2) and (6.3). We let $\mathcal{M}_{0,1} \subset \mathcal{M}_0$ (resp. $\mathcal{M}_{\infty,1} \subset \mathcal{M}_\infty$) denote the collection of $Z \in \mathcal{M}_0$ (resp. $Z \in \mathcal{M}_\infty$) with $\|Z\| < \infty$.

Clearly $\|\cdot : \cdot\|$ is a stronger metric than $d_\gamma$, for any $\gamma \geq 0$ and moreover $\mathcal{M}_{0,1}$ is a complete metric space with respect to $\|\cdot : \cdot\|$.

One important fact regarding $\mathcal{R}$ is the following from [BHZ16] Thm. 6.15.
Theorem 6.2 Any $M \in \mathcal{R}$ defines a map from $\mathcal{M}_\infty$ into itself which associates to a model $Z = (\Pi, \Gamma)$ a renormalised model $Z^M = (\Pi, \tilde{\Gamma})$. This renormalised model satisfies for every $x \in \Lambda$

$$\tilde{\Pi}_x = \Pi_x M .$$  \hspace{1cm} (6.5)

Furthermore, this action of $\mathcal{R}$ extends to a continuous right action on $\mathcal{M}_0$.

6.2 The space of jets

We set $P \overset{\text{def}}{=} \{(t, x) \in \Lambda : t = 0\}$ (thought of as the singular set of a modelled distribution) and define $\mathcal{U}$ as the space of all maps $U : \Lambda \setminus P \to \mathcal{H}^{\text{ex}}$ and $\mathcal{V}$ as the maps $U : \Lambda \setminus P \to \mathcal{H}^{\text{ex}}$. For $U \in \mathcal{U}$ or $U \in \mathcal{V}$, we write $U = (U_t)_{t \in \mathbb{L}_+}$. For $U \in \mathcal{U}$ we also write $U_{(t,p)} = \mathcal{H}^p U_t$ and, by applying the definitions in Section 3.6 pointwise, we define $U^R \in \mathcal{U}$ as well as the tuple of functions $u^U \overset{\text{def}}{=} (u^U_t)_{t \in \mathbb{L}_+}$ (so that $u^U_t : \Lambda \setminus P \to \mathbb{R}$ is given by setting $u^U_t(x) \overset{\text{def}}{=} (X^p, U_t(x)) = (1, U_{(t,p)}(x))$).

For any $F \in \mathcal{C}_0$ we write $F(u^U)$ for the real-valued function on $\Lambda \setminus P$ given by $F(u^U)(x) \overset{\text{def}}{=} F(u^U(x))$.

Following Lemma 3.14, given $U \in \mathcal{V}$, we henceforth write $Q_{\leq \gamma} F(U) \Xi \in \mathcal{V}$ for the element obtained by applying the map $Q_{\leq \gamma} F \Xi$ to $U$ pointwise. Also following Definition 3.15, we say that $U \in \mathcal{V}$ is coherent to order $L$ with $F$ if $U(z)$ is for all $z \in \Lambda \setminus P$.

We record the following simple lemma for the canonical model.

Lemma 6.3 Consider $F \in \mathbb{Q}$, $Z^\xi = (\Pi, \Gamma)$ the canonical model built from some $\xi \in \Omega_\infty$, and an element $U = (U_t)_{t \in \mathbb{L}_+} \in \mathcal{H}^{\text{ex}}$. It holds for all $x \in \Lambda$, $t \in \mathbb{L}_+$, and $\xi = (\hat{\xi}, \varphi) \in \mathcal{D}_t$ that

$$\Pi_x \left[ Q_{\leq 0} F^t(U) \Xi \right](x) = F^t(\varphi(x)) \xi_t(x) ,$$

where $F^t(U)$ is given by (3.7), $\xi_t \overset{\text{def}}{=} \Pi_{(b, \gamma) \in \mathcal{I}} D^\gamma \xi_b$, $\varphi = (\varphi_t)_{t \in \mathbb{L}_+}$ is given by $\varphi_t \overset{\text{def}}{=} \Pi_x U_t$, and $\varphi$ is defined as in (2.12).

Proof. Note that $\Pi_x(U - \langle U, 1 \rangle)^\alpha(x) = 0$ for any $\alpha \in \mathbb{N}^0$ such that $\alpha(\hat{\xi}) > 0$ for some $\hat{\xi} \in \partial_+$. Expanding $F^t$ as in (2.12), the claim follows from the fact that a polynomial is given exactly by its Taylor expansion, as well as the fact that the canonical model is multiplicative, reduced (i.e., ignores the value of the extended label $o$), and compatible with the abstract gradient $\mathcal{D}$ (see [Hai14 Def. 5.26]). \qed

6.3 Modelled distributions

Throughout this subsection we fix $F \in \mathbb{Q}$. Our definitions and results, unless explicitly stated, are given with respect to some arbitrary fixed model $Z \in \mathcal{M}_0$. We often drop dependence on $Z$ from the notation.
For any sector $V$ of the regularity structure $\mathcal{T}$, and any $\gamma, \eta \in \mathbb{R}$, recall that [Hai14, Def. 6.2] defines a corresponding space of singular modelled distributions $D^{\gamma,\eta}_P(V)$ with respect to $Z$ over $\Lambda \setminus P$, with values in the sector $V$. We will often drop the reference to $P$ and $V$ when it is clear from the context. We will also often write $D^{\gamma,\eta}_\alpha$ to emphasise that the underlying sector is of regularity $\alpha \leq 0$.

Denote by $\mathbb{1}_+ : \Lambda \to \{0, 1\}$ the indicator function of the set $\{(t, x) : t > 0\}$, which we canonically identify with an element of $D^{\infty,\infty}_0$. We recall two results from [Hai14].

**Lemma 6.4** Let $\gamma, \alpha, \eta \in \mathbb{R}$, and $t \in \mathcal{L}_+$. Suppose that $\gamma, \eta \notin \mathbb{N}$, $\gamma - |t| > 0$, and $\eta \wedge \alpha > -s_0 + |t|$. Then $K^t_{\gamma-|t|}$, defined by [Hai14] Eq. 5.15 using the smooth kernel $K_t$, is a locally Lipschitz map from $D^{\gamma-|t|, \eta-|t|}(\mathcal{T}^\text{ex}_{\Lambda})$ to $D^{\gamma,\eta\wedge \alpha, |t|}(\mathcal{T}^\text{ex}_{\Lambda})$.

Moreover, for all $\kappa \geq 0$ and $T \in (0, 1]$, it holds that
$$\|K^t_{\gamma-|t|} 1 + f\|_{\gamma; \eta; \alpha; \gamma; \eta, \alpha; |t| + \kappa; T} \lesssim T^{-s_0/\kappa} \|f\|_{\gamma-|t|, \eta-|t| + \kappa; T}$$
for all $f \in D^{\gamma-|t|, \eta-|t|}(\mathcal{T}^\text{ex}_{\Lambda})$, where the proportionality constant depends on $\|Z\|_{\gamma; \eta; \alpha; \gamma; \eta, \alpha; |t| + \kappa}$.

**Proof.** For all $f \in D^{\gamma-|t|, \eta-|t|}(\mathcal{T}^\text{ex}_{\Lambda})$, it holds by definition of $\mathcal{T}^\text{ex}_{\Lambda}$ that $K^t_{\gamma-|t|} f$ is a function from $\Lambda \setminus P$ to $\mathcal{T}^\text{ex}_{\Lambda}$. The conclusion follows at once from [Hai14, Prop. 6.16, Thm. 7.1].

Concerning the initial condition, we recall the following result.

**Lemma 6.5** Let $\alpha \in \mathbb{R}$ such that $\alpha \notin \mathbb{N}$ and $u^0_t \in C^\alpha_\#(T^\text{ex})$. Then the function
$$v_t(t, x) := (G_t u^0_t)(t, x) = \int_{T^\text{ex}} G_t(t, x - y) u^0_t(y) dy$$
lifts canonically to a singular modelled distribution in $D^{\gamma,\alpha}(\mathcal{T}^\text{ex})$ for all $\gamma > \alpha \vee 0$.

**Proof.** Identical to the proof of [Hai14, Lem. 7.5] upon using (2.7).

For $\alpha \in \mathbb{R}$ and $\gamma > 0$, recall the operator $R^\gamma_\alpha : C^\alpha_\#(\Lambda) \to D^{\gamma,\alpha}(\mathcal{T}^\text{ex})$ defined by [Hai14] Eq. 7.7 using the smooth kernel $R_t$. Let $\mathcal{R}$ denote the reconstruction operator\footnote{See [Hai14, Sec. 6.1]} associated to the model $Z$.

For a choice of $\gamma_t, \eta_t \in \mathbb{R}$, with $t \in \mathcal{L}_+$, let us define
$$\mathcal{W}^\gamma_{\gamma, \eta} \overset{\text{def}}{=} \bigoplus_{t \in \mathcal{L}_+} D^{\gamma_t, \eta_t}(\mathcal{T}^\text{ex}_{\Lambda})
$$
which is a subspace of $\mathcal{W}$ by definition.
To formulate the fixed point map, we introduce the operator

$$f \mapsto \mathcal{P}_t 1 + f \overset{\text{def}}{=} (K^t_{\gamma_0 - |t|} + R^t_{\gamma_0} \mathcal{R}) 1 + f,$$

which is a locally Lipschitz map from $\mathcal{D}^{\gamma_0 - |t|, \eta_0 - |t|}_0(\bar{\mathcal{S}}^t_{\psi})$ to $\mathcal{D}^{\gamma_0 - |t|, \eta_0 - |t|}_0(\bar{\mathcal{S}}^t_{\psi})$ for appropriate $\gamma, \eta, \alpha \in \mathbb{R}$ (see Lemma 6.4).

The direct abstract version of the initial value problem (2.13) is given by

$$U_t = \mathcal{P}_t \left[ 1 + Q_{\gamma_0 - |t|} \left( \sum_{l \in \mathcal{D}_t} F^l_{t}(U)\Xi_l \right) \right] + G_t u_0^t, \quad \forall t \in \Sigma_+.$$  \hspace{1cm} (6.6)

In a number of examples, however, one encounters a problem when trying to naively solve (6.6) in $\mathcal{W}^{\gamma, \eta}$. The difficulty comes from the fact that some of the terms $1 + F^l_{t}(U)\Xi_l$ may take values in a sector of regularity $\alpha \leq -s_0$: because of the singularity at $t = 0$, the reconstruction operator $\mathcal{R}$ (and thus the maps $K^t_{\gamma_0 - |t|}$ and $\mathcal{P}_t$) is not a priori well-defined for such terms, see [Hai14 Prop. 6.9]. A related difficulty is that (reconstructions of) solutions to (6.6) can be distribution-valued, and thus one needs additional assumptions guaranteeing that they can be evaluated at a fixed time slice; this is necessary if we wish to restart our fixed point map to obtain a well-posed notion of maximal solution. Both of these difficulties already appear in the $\Phi^4_3$ model [Hai14 Sec. 9.4], where they are dealt with in a somewhat ad hoc manner.

**Remark 6.6** Note that $\mathcal{P}_t 1 + f$ in general makes sense for any singular modelled distribution $f$ for which $\mathcal{R} 1 + f$ can be appropriately defined, see [Hai14 Rem. 6.17]; see also [GH17a] where such problems arise on the boundary of the domain.

### 6.4 Renormalised PDEs

In the scope of the problems we consider, we wish to apply $\mathcal{P}_t$ to modelled distributions $1 + f \in \mathcal{D}^{\bar{\gamma}, \bar{\eta}}_{\alpha}$ with $\alpha \leq -s_0$ (as in, e.g., $\Phi^4_3$ with $d > 2$); however it will always be the case that $\bar{\eta} > -s_0$ (namely by Assumption 2.4 or 6.20), so this parameter will not be a problem. Following Remark 6.6 it suffices to give a canonical definition for $\mathcal{R} 1 + f$ with the expected regularity.

In this subsection, we resolve this issue by assuming that the underlying model $Z$ is smooth and that $1 + f \in \mathcal{D}^{\bar{\gamma}, \bar{\eta}}_{\alpha}$ with $\bar{\gamma} > 0$ and $\bar{\eta} > -s_0$. In this case, one can readily see (e.g., by inspecting the proof of [Hai14 Prop. 6.9]) that $\mathcal{R} 1 + f$ is canonically defined as a continuous function on $\Lambda \setminus P$ with a blow-up of order $\bar{\eta}$ at $P$. As a result, $\mathcal{P}_t 1 + f \in \mathcal{D}^{\bar{\gamma} + |t|, \bar{\eta} + |t|}_0(\bar{\mathcal{S}}_{\psi})$ is likewise canonically defined. (In this case, however, $\mathcal{R} 1 + f$ and $\mathcal{P}_t 1 + f$ will generally fail to be continuous functions of $f$ and the model!) In this case, we also note that

$$\mathcal{R} \mathcal{P}_t 1 + f = G_t \ast \mathcal{R} 1 + f,$$

and, for all $x \in \Lambda \setminus P$,

$$(\mathcal{R} 1 + f)(x) = (\Pi_x (1 + f)(x))(x).$$  \hspace{1cm} (6.8)
With these considerations in mind, we can reformulate the purely algebraic result of Theorem \([3.20]\) in the setting of modelled distributions.

**Theorem 6.7** Fix \(F \in \mathcal{Q}\), \(\xi \in \Omega_\infty\), and \(M \in \mathcal{R}\). Let \(Z = (\Pi, \Gamma) \in \mathcal{M}_\infty\) be the canonical \(K\)-admissible lift of \(\xi\) and write \(\hat{Z} = (\hat{\Pi}, \hat{\Gamma})\) for the renormalised model \(Z^M\) obtained in Theorem 6.2. For each \(t \in \mathcal{L}_+\), let \(\eta_t > -s_0\) and \(\gamma_t \overset{def}{=} \gamma + \text{reg}(t)\) for some fixed \(\gamma \in \mathbb{R}\). Suppose that \(\gamma_t - |t|_s > \gamma_L\), with \(L \overset{def}{=} L_0\) and \(\gamma_L\) defined as in Section 3.3.

Suppose also that there exists \(U \in \mathcal{W}^{\gamma_0}\) with respect to \(\hat{Z}\), defined on an interval \((0, T)\), such that, for each \(t \in \mathcal{L}_+\), there exist \(\hat{\gamma} > 0\) and \(\tilde{\eta} > -s_0\) such that \(1 + \sum_{i \in \mathcal{D}_1} F^i_t(U) \Xi_i\) is an element of \(\mathcal{D}^{\hat{\gamma}, \tilde{\eta}}\). Suppose finally that \(U\) is a solution on \((0, T)\) to the fixed point problem \((6.6)\) with some initial data \(u_{1,0}\).

Then for every \(t \in \mathcal{L}_+\), the function \(u_t \overset{def}{=} RU_t\) is the unique solution on \((0, T)\) to the stochastic PDE
\[
\partial_t u_t = \mathcal{L}_t u_t + \sum_{(i, \sigma) \in \mathcal{D}_1} (MF^i_{t, \sigma})(u) \xi^i_t,
\]
with initial condition \(u_{1,0}\), where \(\xi^i_t \overset{def}{=} \prod_{(i, \sigma) \in \mathcal{D}_1} D^\sigma \xi\) and the tuple \(u = (u_0)_{o \in \mathcal{O}}\) is given by \(u_{(b, q)} \overset{def}{=} \partial^b u_b\).

**Proof.** Let \(t \in \mathcal{L}_+\) and consider the expansion of \(U_t\) as \((3.8)\). Using the condition \(\gamma_t - |t|_s > \gamma_L\) to note that \(p_{L, \mathcal{Q} \leq \gamma_t - |t|_s} = p_{\leq L}\), it follows from the definition of \(K^t_{\gamma_t - |t|_s}\) that
\[
p_{\leq L} \sum_{i \in \mathcal{D}_1} F^i_t(U) \Xi_i = p_{\leq L} U^R_t.
\]
(6.9)

By \((6.7)\), one has
\[
u_t(x) = G_t \ast \left[ \hat{\mathcal{R}}^{1+ \mathcal{Q} \leq \gamma_t - |t|_s} \sum_{i \in \mathcal{D}_1} F^i_t(U) \Xi_i \right] + G_t u_{1,0}.
\]

Since we consider models in \(\mathcal{M}_\infty\), we can use \([\text{Hai} 14\text{ Rem. 3.15}]\) for the term on the right hand side, which yields for any \(x \in \Lambda\)
\[
\hat{\mathcal{R}}^{1+ \mathcal{Q} \leq \gamma_t - |t|_s} \sum_{i \in \mathcal{D}_1} F^i_t(U) \Xi_i(x) = \hat{\Pi}_x \left( \mathcal{R}^{1+ (x) \mathcal{Q} \leq \gamma_t - |t|_s} \sum_{i \in \mathcal{D}_1} F^i_t(U(x)) \Xi_i \right)(x)
\]
\[
= \hat{\Pi}_x \left( p_{\leq L_0} \sum_{i \in \mathcal{D}_1} F^i_t(U(x)) \Xi_i \right)(x) = \hat{\Pi}_x (p_{\leq L_0} U^R_t(x))(x)
\]
\[
= \Pi_x (p_{\leq L_0} MU^R_t(x))(x),
\]
where the first equality uses \((6.8)\), the second equality uses that \(\gamma_t - |t|_s > 0\) and that \(|\tau|_+ > 0\) for every \(\tau \notin \mathcal{W}_{\leq L_0}\), and thus \(\Pi_x (\tau)(x) = 0\), and the third equality uses \((6.9)\) and that \(L \geq L_0\). To obtain the final equality, we used the identity.
\[ \hat{\Pi}_x = \Pi_x M, \] combined with the fact that for all \( \tau \in \mathcal{T}^\text{ex} \) we can write \( M \tau = \sum_i \tau_i \) with \( |\tau_i|_+ = |\tau|_+ \), and thus \( \Pi_x(M \tau)(x) = 0 \) for all \( \tau \notin \mathcal{W}_{\leq L_0} \). Recalling that \( L = L_0 \) and using again that \( |\tau|_+ > 0 \) for all \( \tau \notin \mathcal{W}_{\leq L_0} \), and thus \( \Pi_x(\tau)(x) = 0 \), it follows from (6.9) and Theorem 3.20 that

\[
\Pi_x(p_{\leq L_0} MU_x^R(x))(x) = \Pi_x \left( \sum_{l \in \mathcal{D}_t} (MF)^{(l,o)}(MU(x))\xi_l(x) \right) = \sum_{(l,o) \in \mathcal{D}_t} (MF)^{(l,o)}(u(x))\xi_l(x).
\]

In the first equality we used that \( \Pi_x(p_{\leq L_0} \tau)(x) = \Pi_x(\tau)(x) \). For the second equality, suppose that \( (MF)^{(l,o)} \) depends on \( \mathfrak{X}_{(b,p)} \), i.e., \( D_{(b,p)}(MF)^{(l,o)} \neq 0 \). Then since \( MF \) obeys \( R \) by Lemma 2.17, it holds that \( \text{reg}(t) < |l_b| + |s|_+ + \text{reg}(b) - |p|_s \). Since \( \gamma_t - |l_b| > 0 \), it follows by definition of \( \gamma_b \) that \( \gamma_b - |p|_s > 0 \). By [Hai14 Prop. 5.28] and the fact that \( M \) commutes with \( \mathcal{D}^p \), we obtain

\[
(\Pi_x \mathcal{D}^p MU_b(x))(x) = (\hat{\Pi}_x \mathcal{D}^p U_b(x))(x) = (\hat{R} \mathcal{D}^p U_b)(x) = \mathcal{D}^p u_b(x),
\]
whence the conclusion follows from Lemma 6.3.

### 6.5 Generalised Da Prato–Debussche trick

In this subsection, we address the issues discussed at the end of Section 6.3 in a way which is stable under taking limits of models. We do so by finding an appropriate space of modelled distributions and making a few additional assumptions on the regularity structure and models, which allow us to perform a version of the Da Prato–Debussche trick [DPDo2, DPDo3]. In contrast to Section 6.4, this method does not rely on the smoothness of the underlying model and retains continuity of the fixed point with respect to the model; we reconcile the two viewpoints in Proposition 6.22 below.

Consider \( t \in \mathcal{L}_+ \). As in Definition 2.0, we say that \( \tau \in \mathcal{T}^\text{ex} \) of the form (3.5) is \( t \)-non-vanishing for \( F \) if \( \partial^j \prod_{j=1}^n D_{o_j}F_t^{(j)} \neq 0 \) and \( \tau_j \) is \( t_j \)-non-vanishing for every \( j = 1, \ldots, n \). Note that if \( \tau \) is \( t \)-non-vanishing, then every subtree \( \tilde{\tau} \) of \( \tau \) with \( \partial_{\tilde{\tau}} = \partial_\tau \) is also \( t \)-non-vanishing. Furthermore, we define

\[
\mathcal{T}_t^F \overset{\text{def}}{=} \{ \tau \in \mathcal{T}_t^{\text{ex}} : \text{\( \tau \) is \( t \)-non-vanishing} \}, \quad \mathcal{F}_t^F \overset{\text{def}}{=} \text{Span} \mathcal{T}_t^F.
\]

Let \( \Xi_t^R \subset \mathcal{R} \) denote the subspace of those functions taking values in \( \mathcal{T}_t^{\text{ex}} \overset{\oplus}{+} \bigoplus_{l \in \mathcal{L}_+} \mathcal{F}_{(l,0)[\mathcal{T}_t^F]} \).

**Remark 6.8** \( \mathcal{T}_t^F \) is in general not invariant under the action of \( M \in \mathcal{R} \) on \( F \in \mathcal{Q} \) defined in Section 3. For example, if \( F_t^l = 0 \), then \( \Xi_t \notin \mathcal{T}_t^F \), but it is possible

\[ \tag{16} \text{As before, by a subtree, we mean that} \mathcal{T}_t^R \text{ is a tree whose node and edge sets are subsets of those of} \mathcal{T}_t^R \text{ and whose decorations satisfy} \bar{f} = f(e) \text{ for all} e \in E_F, \text{ and} \bar{m}^x = m^x \text{ and} \bar{m}^x(x) \leq m^x(x) \text{ for all} x \in N_F. \]
that \((MF)_t^1 \overset{\text{def}}{=} \Upsilon^F_t[M^*\Xi_t] \neq 0\) and \(\Xi_t \in \tilde{T}_t^\text{ex}\), so that \(\Xi_t \in \mathcal{T}_t^{MF}\) (this can occur naturally when \(I = (0,e) \in \mathcal{D}_t\), i.e., \(\Xi_t\) is a “purely extended decoration” noise). However this does not cause issues for proving our main theorem – while the notion of \(t\)-non-vanishing is used to ensure that we can solve the fixed point problem associated to \(F\), we never try to solve a fixed point problem associated with \(MF\).

Lemma 6.9 Let \(t \in \mathcal{L}_+\). Then \(\tilde{T}_t^\text{ex} \oplus \mathcal{T}_t^F\) and \(\tilde{T}_t^\text{ex} \oplus \mathcal{J}_{(t,0)}[\mathcal{T}_t^F]\) are sectors of \(\bar{T}\). Moreover, for every \(I \in \mathcal{D}_t\), \(\gamma \in \mathbb{R}\), and \(U \in \mathcal{U}_0\), it holds that \(\mathbb{Q}_{\leq \gamma} F_t^1(U) \Xi_t\) is a map from \(\Lambda \setminus \bar{P}\) to \(\tilde{T}_t^\text{ex} \oplus \mathcal{T}_t^F\).

Proof. Consider \(\tau \in \mathcal{T}_t^F\) and write \(\Delta_{t,0}^\text{ex}\mathcal{J}_{(t,0)}[\tau] = \sum_k \tau^{(1)} \otimes \tau^{(2)}\) with \(\Delta_{t,0}^\text{ex}\) defined in [BHZ16]. To show that \(\tilde{T}_t^\text{ex} \oplus \mathcal{J}_{(t,0)}[\mathcal{T}_t^F]\) is a sector, it suffices to show that \(\tau^{(1)} \in \tilde{T}_t^\text{ex} \oplus \mathcal{J}_{(t,0)}[\mathcal{T}_t^F]\). If \(\tau^{(1)} = X^k\) for some \(k \in \mathbb{N}^{d+1}\), this is clear. Otherwise, we necessarily have \(\tau^{(1)} = \mathcal{J}_{(t,0)}[\tau]\), where \(\tau \in \tilde{T}_t^\text{ex}\) is a subtree of \(\tau\) with \(\wp_t = \wp_{\tau}\) (indeed, note that the “driver” decorations of \(\tilde{\tau}\) and \(\tau\) necessarily match due to the projection onto the positive trees in the definition of \(\Delta_{t,0}^\text{ex}\)). Since \(\tau \in \mathcal{T}_t^F\) by assumption, it follows that \(\tilde{\tau} \in \mathcal{T}_t^F\), and thus \(\tilde{T}_t^\text{ex} \oplus \mathcal{J}_{(t,0)}[\mathcal{T}_t^F]\). The argument to show that \(\tilde{T}_t^\text{ex} \oplus \mathcal{T}_t^F\) is a sector is similar and simpler.

For the second claim, consider a tree \(\tau \in T_t^F\), written as \((3,5)\), which appears with a non-zero coefficient in the expansion of \(F_t^1(U)\Xi_t\). By Lemma 3.14 it suffices to show that \(\tau\) is \(t\)-non-vanishing.

We note that since \(U \in \mathcal{U}_0\) it holds that \(\tau_t \in \mathcal{T}_t^F\) for all \(i = 1, \ldots, n\), thus it suffices to show that \(\partial^k(\prod_{j=1}^n D_{\alpha_j}) F_t^1 \neq 0\). If \(k = 0\), this is directly a consequence of the fact that \(\tau\) appears with a non-vanishing coefficient. Similarly, if \(k \neq 0\), we know that there must be some \(\alpha \in \mathbb{N}^0\), \(\alpha \neq 0\), such that \(D^\alpha(\prod_{j=1}^n D_{\alpha_j}) F_t^1 \neq 0\). However, this means that \(\prod_{j=1}^n D_{\alpha_j} F_t^1\) is not a constant and we get the desired result by applying Lemma 2.1. \(\square\)

It follows that the natural space in which to solve the fixed point problem (6.6) is

\[
\mathcal{U}_0^{\gamma,\eta} \overset{\text{def}}{=} \mathcal{U}^{\gamma,\eta} \cap \mathcal{U}_0 = \bigoplus_{t \in \mathcal{L}_+} \mathcal{D}^{\gamma,\eta} \left( \tilde{T}_t^\text{ex} \oplus \mathcal{J}_{(t,0)}[\mathcal{T}_t^F] \right).
\]

In order to guarantee that this problem is well-posed we make the following assumption which is natural in view of the discussion above.

Assumption 6.10 For every \(t \in \mathcal{L}_+\), every \(T = T_t^m \in \tilde{T}_t^\text{ex}\) which is \(t\)-non-vanishing, and every subtree \(\mathcal{T}_t^m\) of \(T\) with \(\mathcal{T}_t^m \neq T_t^m\) and \(\wp_T = \wp_{\mathcal{T}_t^m}\), one has \(|\mathcal{T}_t^m|_+ > -(|t|_\alpha \wedge \delta_0)\).

Remark 6.11 Since every tree in \(\tilde{T}_t^\text{ex}\) with a non-zero extended decoration came from contracting a subforest of another tree in \(\tilde{T}_t^\text{ex}\) with identically zero extended decorations (see [BHZ16 Lem. 5.25]), an equivalent version of Assumption 6.10 is to replace \(|\mathcal{T}_t^m|_+ > -(|t|_\alpha \wedge \delta_0)\) with \(|\mathcal{T}_t^m|_- > -(|t|_\alpha \wedge \delta_0)\).
We will see below that Assumption [6.10] allows us to remove all the planted negative trees in the expansion of the solution to [6.6] and solve for the remainder as a modelled distribution taking values in a function-like sector; this procedure can be seen as performing the Da Prato–Debussche trick [DPDo3] at the level of modelled distributions.

For $t \in \mathcal{L}_+$, define
\[
\mathcal{T}^F_{t,-} \overset{\text{def}}{=} \mathcal{T}^F \cap \mathcal{T}^{ex}_{\leq -(|l|_a \land s_0)} , \\
\mathcal{T}^F_{t,+} \overset{\text{def}}{=} \text{Span } \mathcal{T}^F_{t,-} = \mathcal{T}^F \cap \mathcal{T}^{ex}_{\leq -(|l|_a \land s_0)} , \\
\mathcal{T}^F_{t,+} \overset{\text{def}}{=} \mathcal{T}^F \setminus \mathcal{T}^F_{t,-} , \\
\mathcal{T}^F_{t,+} \overset{\text{def}}{=} \text{Span } \mathcal{T}^F_{t,+} .
\]

We suppose for the remainder of the section that Assumption [6.10] holds.

**Lemma 6.12** Let $t \in \mathcal{L}_+$. Then $\Gamma \tau = \tau$ for every $\Gamma \in G$ and $\tau \in \mathcal{T}^F_{t,-}$.

**Proof.** It suffices to show that $\Delta_{ex}^+ \tau = \tau \otimes 1$ for every $\tau \in \mathcal{T}^F_{t,-}$. Writing $\Delta_{ex}^+ \tau = \sum \tau_1^{(1)} \otimes \tau_1^{(2)}$, it holds that $\tau_1^{(1)}$ is a subtree of $\tau$. Suppose $\tau_1^{(1)}$ is a strict subtree of $\tau$. By Assumption [6.10] we have $|\tau_1^{(1)}|_+ \geq -(|l|_a \land s_0)$. On the other hand, since $|\tau|_+ \leq -(|l|_a \land s_0)$ and $\Delta_{ex}^+$ preserves the $|\cdot|_+$-degree, this would imply that $|\tau_1^{(2)}|_+ < 0$, which is impossible, hence $\Delta_{ex}^+ \tau = \tau \otimes 1$ as desired.

**Lemma 6.13** Let $t \in \mathcal{L}_+$. Then $\mathcal{F}^{ex} \oplus \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$ and $\mathcal{F}^{ex} \oplus \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$ are sectors of $\mathcal{F}$ of respective regularities 0 and $-(|l|_a \land s_0) + \kappa$ for some $\kappa > 0$.

**Proof.** By definition of $\mathcal{T}^F_{t,+}$, we only need to show that $\mathcal{F}^{ex} \oplus \mathcal{F}^F_{t,+}$ and $\mathcal{F}^{ex} \oplus \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$ are sectors. We only show that the latter is a sector since the argument for the former is identical.

Let $\tau \in \mathcal{T}^F_{t,+}$. Writing $\Delta_{ex} \mathcal{F}_{(t,0)}[\tau] = \sum \tau_1^{(1)} \otimes \tau_1^{(2)}$, it suffices to show that $\tau_1^{(1)} \in \mathcal{F}^{ex} \oplus \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$. If $\tau_1^{(1)} = \mathcal{X}^k$ for some $k \in \mathbb{N}^{d+1}$, this is clear. Otherwise $\tau_1^{(1)} = \mathcal{F}_{(t,0)}[\tilde{\tau}]$ for some subtree $\tilde{\tau}$ of $\tau$ with $\theta_{\tilde{\tau}} = \theta_{\tau}$. In particular, $\tilde{\tau}$ is $t$-non-vanishing. If $\tilde{\tau} = \tau$, then evidently $\tau_1^{(1)} \in \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$. If $\tilde{\tau} \neq \tau$, then, by Assumption [6.10] $|\tilde{\tau}|_+ > -(|l|_a \land s_0)$, and so again $\tau_1^{(1)} \in \mathcal{F}_{(t,0)}[\mathcal{T}^F_{t,+}]$ as desired.

**Lemma 6.14** $\Upsilon_{t}^{F}[\tau]$ is a constant for every $t \in \mathcal{L}_+$ and $\tau \in \mathcal{T}^F_{t,-}$.

**Proof.** Suppose that $\Upsilon_{t}^{F}[\tau]$ is not constant for some $t \in \mathcal{L}_+$ and $\tau \in \mathcal{T}^F_{t,-}$. Consider $\hat{i}$ from Definition [5.7] below and write $\hat{i} \tau = \sum_j c_j \tau_j$, where $c_j \in \mathbb{R}, \tau_j \in \mathcal{T}^{ex},$ and $\tau$ is a strict subtree of $\tau_j$ with $\theta_\tau = \theta_{\tau_j}$. It follows from Lemma [5.1] that $\partial_i \Upsilon_{t}^{F}[\tau] \neq 0$ for every $i \in \{0, \ldots, d\}$, and thus, by Corollary [5.2], $\Upsilon_{t}^{F}[\hat{i} \tau] \neq 0$. Hence, for some $j$, $\Upsilon_{t}^{F}[\tau_j] \neq 0$ and thus $\tau_j$ is $t$-non-vanishing. It follows by Assumption [6.10] that $|\tau_j|_+ > -(|l|_a \land s_0)$, which concludes the proof.

[17]While there is similarity to the trick of [DPDo3], our version of the trick plays a different and less central role here: in general the abstract equation we arrive at for our remainder will involve products that, viewed concretely, are still classically ill-defined.
Let $\mathcal{W}_+$ denote the space of functions from $\Lambda \setminus P$ to $\bigoplus_{t \in \mathcal{L}_+} \left( \mathcal{T}_{\text{ex}}^F + \mathcal{J}_{(0);0}(\mathcal{T}_{\text{ex}}^F) \right)$, noting that $\mathcal{W}_+$ is a subspace of $\mathcal{W}_0$. Let $\tilde{U} \in \mathcal{W}_0$ denote the unique constant function for which, for every $t \in \mathcal{L}_+$ and $\tau \in \mathcal{T}_{\text{ex}}$,

$$
\langle \tilde{U}, \tau \rangle = \begin{cases} 
\mathcal{Y}_t^F(\tau) & \text{if } \tau \in \mathcal{T}_{\text{ex}}^F ; \\
0 & \text{otherwise} ;
\end{cases} \quad (6.10)
$$

(in particular, $\tilde{U}$ takes values in $\mathcal{T}_{\text{ex}}^F$).

**Lemma 6.15** For any $V \in \mathcal{W}_+$, if one defines $U \in \mathcal{W}_0$ via $U_b \overset{\text{def}}{=} V_b + [\mathcal{J}_{(0);0}(\tilde{U}_b)]$ for each $b \in \mathcal{L}_+$, then one has, for every $t \in \mathcal{L}_+$,

$$
Q_{\leq -(|t|_s \wedge s_0)} \sum_{l \in \mathcal{D}_t} F^t_1(U) \Xi_l = \tilde{U}_t .
$$

**Proof.** Fix $t \in \mathcal{L}_+$ and $l \in \mathcal{D}_t$. Suppose one has a tree $\tau \in \mathcal{T}_{\text{ex}}$, written as $\mathcal{T}_{\text{ex}}$, which appears with a non-zero coefficient in the expansion of $F^t_1(U) \Xi_l$. Note that $\tau \in \mathcal{T}_{\text{ex}}^F$ by Lemma 6.9.

Suppose that $|\mathcal{J}_{(t);p_l}(\tau_l)|_+ \geq 0$ for some $i = 1, \ldots, n$. Let $\bar{\tau}$ be the strict subtree of $\tau$ formed by removing the branch $\mathcal{J}_{(t);p_l}(\tau_l)$ from $\tau$. Then, by Assumption 6.10, $|\bar{\tau}|_+ > -(|t|_s \wedge s_0)$, which in particular implies that $|\tau|_+ > -(|t|_s \wedge s_0)$. Likewise, suppose $k \neq 0$. Let $\bar{\tau}$ be the strict subtree of $\tau$ formed by setting the polynomial decoration at the root of $\tau$ to zero. Then, by Assumption 6.10, $|\bar{\tau}|_+ > -(|t|_s \wedge s_0)$, which again implies $|\tau|_+ > -(|t|_s \wedge s_0)$. Therefore, for every $t \in \mathcal{L}_+$, $l \in \mathcal{D}_t$, and every $\tau$ appearing in the expansion of $F^t_1(U) \Xi_l$, it holds that $\tau$ has no polynomial decoration at the root or branches of non-negative $| \cdot |_+$-degree. It follows that

$$
Q_{\leq -(|t|_s \wedge s_0)} \sum_{l \in \mathcal{D}_t} F^t_1(U) \Xi_l = Q_{\leq -(|t|_s \wedge s_0)} \sum_{l \in \mathcal{D}_t} F^t_1((\mathcal{J}_{(0);0}(\tilde{U}_b)) + \langle V_b, 1 \rangle)_{b \in \mathcal{L}_+} \Xi_l .
$$

(6.11)

Since the RHS of (6.11) does not depend on the coefficient in $U$ of any tree of positive order, we may assume without loss of generality that $U$ is coherent. It then follows from Lemma 6.10 that the LHS is precisely $\tilde{U}_t$. □

In order to work “at stationarity” as described in Remark 2.15, we want to define, for each $t \in \mathcal{L}_+$ and $\tau \in \mathcal{T}_{\text{ex}}^F$, $\mathcal{P}_t \tau$ as an appropriately continuous function of the underlying model. This requires some work since the action of $\mathcal{P}_t$ may not be local.

Throughout this section we have assumed that we have fixed differential operators $\langle \mathcal{L}_t \rangle_{t \in \mathcal{L}_+}$ as in the beginning of Section 2.6 and then a truncation of the corresponding Green’s functions as described at the beginning of Section 6.1. Using an appropriately designed partition of unity, we assume that for each $t \in \mathcal{L}_+$, we have fixed a decomposition $R_t = \sum_{m=0}^{\infty} R_{t,m}$ where for each $t \in \mathcal{L}_+$ and $m \in \mathbb{Z}$
one has $R_{t,m}$ smooth and supported on $\mathcal{R}_m$ (where $\mathcal{R}_m$ was defined in (6.4)), and such that for each $k \in \mathbb{N}^{d+1}$ one has, for some $\chi > 0$,
\[
\sup_m \sup_{z \in \Lambda} e^{\chi m} \cdot |(D^k R_{t,m})(z)| < \infty.
\]

With these notations, one has the following straightforward fact.

**Lemma 6.16** For any $Z \in \mathcal{M}_{0,1}$, $t \in \mathcal{L}_+$, and $\tau \in T^F_{t-,}$
\[
r^Z_{t,\tau} \equiv \lim_{N \to \infty} \sum_{j=0}^{N} R_{t,j} \ast (R^Z \tau)
\]
converges in $C^\infty(\Lambda)$. Moreover, the map $Z \mapsto r^Z_{t,\tau}$ is a continuous map from $\mathcal{M}_{0,1}$ into $C^\infty(\Lambda)$.

**Proof.** We fix $t \in \mathcal{L}_+$ and $\tau \in T^F_{t-}$. By Lemma [6.12] the structure group acts trivially on $\tau$, and so for any $Z = (\Pi, \Gamma) \in \mathcal{M}_0$ one has $(R^Z \tau)(\cdot) = \Pi \tau(\cdot) \in C^{|\tau|}_\ast$ where $\Lambda$ is arbitrary.

One immediately has the bounds
\[
\|R^Z \tau\|_{|\tau|_+} \lesssim \|Z\|_{R^\tau} \quad \text{and} \quad \|(R^Z - R^Z_\ast \tau)\|_{|\tau|_+} \lesssim \|Z; \bar{Z}\|_{R^\tau},
\]
uniform in the choice of compact set $\mathcal{R} \subset \Lambda$, and $Z, \bar{Z} \in \mathcal{M}_0$. The norms on the LHS’s of (6.13) are those of (6.11). Below, all of our estimates are uniform in $Z \in \mathcal{M}_0$. It is straightforward to see that one has the bound
\[
|(R^Z \tau)(f)| \lesssim \|Z\|_{\mathcal{R}_n} \sup_{k \in \mathbb{N}^{d+1}} \|D^k f(z)|,
\]
uniformly in $n \in \mathbb{Z}$, and over all test functions $f$ supported on $\mathcal{R}_n$. Therefore, for any $n \in \mathbb{Z}$, $k \in \mathbb{N}^{d+1}$, and uniformly over $z \in \mathcal{R}_n$, one has the estimate
\[
\sum_{j=0}^{N} |(D^k R_{t,j} \ast (R^Z \tau))(z)| \lesssim \sum_{j=0}^{N} e^{-\chi j} \|\bar{Z}\|_{\mathcal{R}_{n-j} - 1} + \|Z\|_{\mathcal{R}_{n-j}} + \|Z\|_{\mathcal{R}_{n-j+1}}.
\]
Clearly if $Z \in \mathcal{M}_{0,1}$ the RHS above is absolutely convergent as one takes $N \to \infty$. This establishes the convergence of (6.12) in $C^\infty(\Lambda)$. The statement about continuity follows by using the second bound of (6.13) as input for the same argument.

**Remark 6.17** Here and in the rest of the section, we use $Z$ as a superscript when we want to stress the dependence of some object on the underlying model $Z$.

The following result is immediate from Lemmas [6.12] and [6.16].
Proposition 6.18 Let $Z \in \mathcal{M}_{0,1}$, $t \in \Sigma_+$, and $\tau \in \mathcal{T}_t^F$. Then the constant function $z \mapsto \mathcal{J}(t,0)[\tau]$ is an element of $D^\infty$. Moreover, there exists a smooth $r_{t,\tau}^Z \in C^\infty(\Lambda)$, which we treat canonically as an element of $D^\infty(\mathcal{F}^{\text{ex}})$, with the following properties.

1. Setting,

$$\mathcal{P}_t^Z \tau \overset{\text{def}}{=} \mathcal{J}(t,0)[\tau] + r_{t,\tau}^Z \in D^\infty(\mathcal{F}^{\text{ex}} \oplus \mathcal{J}(t,0)[\mathcal{F}_t^F]),$$

the distribution $f_{t,\tau}^Z \overset{\text{def}}{=} \mathcal{R}^Z \mathcal{P}_t^Z \tau \in C^{[|r|]+||r||+}(\Lambda)$ solves

$$\partial_0 f_{t,\tau}^Z = \mathcal{L}_t f_{t,\tau}^Z + \mathcal{R}^Z \tau.$$

2. The map $Z \mapsto f_{t,\tau}^Z$ is continuous with respect to the metric on $\mathcal{M}_{1,\infty}$.

A consequence of Proposition 6.18 is that, for any $Z \in \mathcal{M}_{0,1}$, we can define $\mathcal{P}_t^Z \mathcal{U}_t \in D^\infty$, and thus $\mathcal{P}_t^Z \xi \in \mathcal{U}_0$ by setting $(\mathcal{P}_t^Z \mathcal{U}_t) \overset{\text{def}}{=} \mathcal{P}_t^Z \mathcal{U}_t$. Moreover, the map $Z \mapsto \mathcal{P}_t^Z \mathcal{U}_t$ is a continuous map from $\mathcal{M}_{0,1}$ to $\bigoplus_{t \in \Sigma_+} D^\infty$.

Rather than seeking a solution $U \in \mathcal{U}$ to (6.6), we instead treat $U$ as a perturbation of the stationary solution by writing

$$U_t = V_t + \mathcal{P}_t U_t, \quad \forall t \in \Sigma_+,$$

(6.14)

where $V_t$ is function-like. More precisely, let us fix

$$\gamma_t \overset{\text{def}}{=} \gamma + \text{reg}(t), \quad \eta_t \overset{\text{def}}{=} \eta + \text{ireg}(t),$$

for some $\gamma, \eta \in \mathbb{R}$, and define the space

$$\mathcal{U}_t^{\gamma,\eta} \overset{\text{def}}{=} \mathcal{U}_t \cap \mathcal{U}_0^{\gamma,\eta} = \bigoplus_{t \in \Sigma_+} D^{\gamma,\eta} (\mathcal{F}^{\text{ex}} \oplus \mathcal{J}(t,0)[\mathcal{F}_t^F]).$$

For $t \in \Sigma_+$, let $\mathcal{U}_t$ denote the space of all maps $U : \Lambda \setminus P \to \mathcal{F}^{\text{ex}}$ (so that $\mathcal{U} = \bigoplus_{t \in \Sigma_+} \mathcal{U}_t$), and consider the map $H_t : \mathcal{U} \to \mathcal{U}_t$ given by

$$H_t(V) \overset{\text{def}}{=} \sum_{t \in \mathcal{D}_t} F_t(V + \mathcal{P} \mathcal{U}) \mathcal{E}_t - \mathcal{U}_t.$$

The following lemma makes precise the gain in regularity obtained by considering the remainder $V$. For $t \in \Sigma_+$, define the quantity $\bar{n}_t$ as in (2.6), but with $|t|$ replaced by $|t|_+$ and the first min taken instead over $t \in \mathcal{D}_t$.

Lemma 6.19 Let $0 \leq \eta \leq \gamma$ and $t \in \Sigma_+$. Then there exists $\kappa_t > 0$ sufficiently small, depending only on the rule $R$ and functions $\text{reg}$ and $\text{ireg}$, such that $H_t$ is a locally Lipschitz map

$$\mathcal{U}_t^{\gamma,\eta} \to D^{\gamma,\eta+\kappa_t,\eta+\bar{n}_t} (\mathcal{F}^{\text{ex}} \oplus \mathcal{J}_t^F).$$
Proof. Note that, for every $V \in \mathcal{H}_+$, $H_t(V)$ is indeed a function from $\Lambda \setminus P$ to $\mathcal{F}^\alpha \otimes \eta^\alpha_t$ due to Lemma 3.15. Fix $t \in D_t$ and consider a term $F(\xi)\tilde{\xi}^\alpha$ in the expansion (6.3) of $F_t$. Write $U \equiv V + \mathcal{P} \tilde{U}$. Since $\tilde{U}_t \in D^{r,\infty}$, it remains only to show that

$$Q_{\leq 0} \bar{F}(U)U^\alpha \Xi_t \in D^{r,|l|_+ + \kappa_t, \eta + \bar{\eta}}. \tag{6.15}$$

Suppose first that $\bar{F}$ is not identically constant. Note that, by Lemma 3.13, $\mathcal{F}^\alpha$ is a sector of regularity $\text{reg}(b) \wedge 0$. Note also that

$$\mathcal{D}^\beta U_b \in D^{\gamma + \text{reg}(b,p), \eta_b - |p|_a} (\mathcal{D}^p \mathcal{F}^\alpha b).$$

If $\text{reg}(b, p) > 0$, then the sector $\mathcal{D}^p \mathcal{F}^\alpha b$ is function-like. Recall also that in this case $0 \leq \eta \leq \eta_b - |p|_a \leq \gamma + \text{reg}(b, p)$. It follows from [Hai14, Prop. 6.13] that

$$Q_{< \gamma} \bar{F}(U) \in D^{\gamma, \eta}_0.$$

Writing

$$U^\alpha = \prod_{(t,p) \in \alpha} \mathcal{D}^p U_t, \quad \mathcal{D}^p U_t \in D^{\gamma + \text{reg}(t,p), \eta + \text{reg}(t,p)}_{\text{reg}(t,p)},$$

it follows from [Hai14] Prop. 6.12 that

$$U^\alpha \in D^{\gamma + \sum_{o \in \alpha} \text{reg}(o), \eta + \sum_{o \in \alpha} \text{reg}(o) \wedge \text{irreg}(o)}.$$ Finally, note that $\Xi_t \in D^{r,\infty}$. Combining everything, we obtain

$$U^\alpha \Xi_t Q_{< \gamma} \bar{F}(U) \in D^{\gamma + |l|_+ + \sum_{o \in \alpha} \text{reg}(o), \eta + |l|_+ + \sum_{o \in \alpha} \text{reg}(o) \wedge \text{irreg}(o)}.$$ Since $F$ obeys the rule $R$, we can find $\kappa_t > 0$ such that

$$\text{reg}(t) - |l|_a + \kappa_t \leq |l|_+ + \sum_{o \in \alpha} \text{reg}(o).$$

By considering the regularity of the relevant sectors (and decreasing $\kappa_t$ if necessary), we see that

$$Q_{\leq 0} \bar{F}(U)U^\alpha \Xi_t = Q_{< \gamma} \bar{F}(U)U^\alpha \Xi_t \left[ U^\alpha \Xi_t Q_{< \gamma} \bar{F}(U) \right],$$

which proves (6.15).

Suppose now that $\bar{F}$ is identically constant. Then expanding $(V + \mathcal{P} \tilde{U})^\alpha \Xi_t$, the term $(\mathcal{P} \tilde{U})^\alpha \Xi_t$ is an element of $D^{\infty}$. On the other hand, using that $V_0 \in D^{\gamma + |l|_+ + \sum_{o \in \alpha} \text{reg}(o), \eta + \bar{\eta}_t}$, we see that every other term is in $D^{\gamma + |l|_+ + \sum_{o \in \alpha} \text{reg}(o), \eta + \bar{\eta}_t}$, which again proves (6.15). \qed

In light of the above lemmas, it is natural to consider an analogue of Assumption 2.4.
Assumption 6.20 Assumption [2,4] holds with $n_t$ replaced by $\bar{n}_t$.

We now take $\gamma$ sufficiently large and $\eta_t = \text{ireg}(t)$, and write the fixed point problem for the remainder $V$ in the space $\mathcal{U}_+^{\gamma,\eta}$, with initial condition $v_0^1$ at time $s \geq 0$, as

$$V_t \mapsto \mathcal{P}_t \left[ \mathbb{1}_+ H_t(V) \right] + G_t v_0^1, \quad \forall t \in \mathcal{L}_+, \quad (6.16)$$

where $\mathbb{1}_+$ denotes the indicator function of the set $\{(t,x) \in \Lambda : t > s\}$. It follows from Lemmas 6.4, 6.5 and 6.10 as well as Assumption 6.20 that the fixed point (6.16) is well-posed and admits local solutions in the space $\mathcal{U}_+^{\gamma,\eta}$ for any initial condition $(v_0^1)_{t \in \mathcal{L}_+} \in \mathcal{C}_{\text{reg}}$. Moreover, since $V_t$ takes values in a function-like sector, the formulation (6.16) allows us to restart the fixed point to obtain maximal solutions\footnote{The fact that local solutions can be patched together in a consistent way follows from an argument identical to [Hai14, Prop. 7.11]}. i.e., up to the blow-up time of $\mathcal{R}V$.

Note that we restricted most of our discussion above to one fixed model $Z$. One can of course extend all the results to obtain continuity properties of the fixed point with respect to the model (the only extension which doesn’t immediately follow from [Hai14] is Lemma 6.10, for which one can use [HP15, Prop. 3.11]). We summarise the above discussion along with the remaining necessary results from [Hai14] in the following theorem.

Theorem 6.21 Let $\gamma \in \mathbb{R}$, and set $\gamma_t \overset{\text{def}}{=} \gamma + \text{reg}(t)$ and $\eta_t \overset{\text{def}}{=} \text{ireg}(t)$. Suppose that Assumptions [6.10] and [6.20] hold, and that $\gamma_t - |t|_s > 0$ and $\gamma_t, \eta_t \notin \mathbb{N}$ for all $t \in \mathcal{L}_+$. Then the following statements hold.

1. For any model $Z = (\Pi, \Gamma) \in \mathcal{M}_{0,1}$ and periodic initial data $v_0 = (v_0^1)_{t \in \mathcal{L}_+} \in \mathcal{C}_{\text{reg}}$, the fixed point problem (6.16) is well posed and admits a local in time solution $V^Z \in \mathcal{U}_+^{\gamma,\eta}$.
2. It holds that $\mathcal{R}V \in \mathcal{C}_{\text{rem}}$, and $V$ is defined on the interval $(0, T(\mathcal{R}V))$.
3. The map $(v_0, Z) \mapsto \mathcal{R}^Z V^Z$ is continuous from $\mathcal{C}_{\text{reg}} \times \mathcal{M}_{0,1}$ into $\mathcal{C}_{\text{rem}}$ when $\mathcal{M}_{0,1}$ is equipped with the metric $\| \cdot \|$.

It remains to connect the remainder $V$ with some abstract fixed point equation to which we can apply Theorem 6.7. For simplicity, we will only do this in the case where $Z \in \mathcal{M}_{\infty,1}$ so that the reconstruction of all relevant modelled distributions are continuous functions. Note that, in this case, one can canonically define $\mathcal{P}_t^Z \mathbb{1}_+ U_t$, and that the distributions $f_{r,t}$ from Proposition 6.18 are in fact smooth functions. In the following result, we implicitly restrict all modelled distributions to the domain $(-\infty, T] \times \mathbb{T}^d$ where $T > 0$ is such that $V^Z$ blows up after time $T$.

Proposition 6.22 Suppose we are in the setting of Theorem 6.21. Let $Z \in \mathcal{M}_{\infty,1}$, $v_0 \in \mathcal{C}_{\text{reg}}$, and consider the functions $U^Z \overset{\text{def}}{=} V^Z + \mathcal{P}_t^Z U \in \mathcal{U}_+^{\gamma,\eta}$ and $\overline{U}^Z \overset{\text{def}}{=} \mathbb{1}_+ U^Z$.\footnote{The fact that local solutions can be patched together in a consistent way follows from an argument identical to [Hai14, Prop. 7.11]}
For every $t \in \Sigma_+$, set
\[
\bar{u}_0^{Z,t} \overset{\text{def}}{=} \sum_{\tau \in \mathcal{T}_{i,t}} \frac{\mathcal{T}_F^{\bar{Z}}[\tau]}{\langle \tau, \bar{\tau} \rangle} f_{\tau,t}(0, \cdot) \in C^\infty(\mathbb{T}^d).
\]
It then holds that
\[
\mathcal{U}_t^Z = V_t^Z + \mathcal{P}^Z_t 1_+ \bar{U}_t + G_t \bar{u}_0^{Z,t}, \quad \forall t \in \Sigma_+.
\label{eq:6.17}
\]
Furthermore, $\mathcal{U}_t^Z$ solves the fixed point problem
\[
\mathcal{U}_t^Z = \mathcal{P}^Z_t \left[1_+ \mathcal{Q}_{\leq \gamma} - \mathbb{I}_t \right] \sum_{l \in \mathcal{L}_t} F_l^t (\mathcal{U}_t^Z) \Xi_l ] + G_t v_0^t + G_t \bar{u}_0^{Z,t}, \quad \forall t \in \Sigma_+.
\label{eq:6.18}
\]
In particular, $\mathcal{U}_t^Z$ falls under the scope of Theorem 6.7.

**Proof.** To show \eqref{eq:6.17} we show that $\mathcal{P}^Z_t 1_+ \bar{U}_t + G_t \bar{u}_0^{Z,t} = 1_+ \mathcal{P}^Z \bar{U}$. It follows directly from definitions that the two sides agree on all non-polynomial trees, so it suffices to show that their reconstructions coincide (see [Hai14, Prop. 3.29]). However, we see that the reconstruction of either side satisfies the PDE
\[
\partial_0 u = \mathcal{L}_t u + \mathcal{R}^Z \bar{U}_t
\]
for all $t > 0$ with initial condition given by $u_0 = \bar{u}_0^{Z,t}$, and thus must be equal.

We now check that $\mathcal{U}_t^Z$ satisfies \eqref{eq:6.18}. It holds that
\[
\mathcal{U}_t^Z = V_t^Z + \mathcal{P}^Z_t 1_+ \bar{U}_t + G_t \bar{u}_0^{Z,t}
\]
\[
= \mathcal{P}^Z_t 1_+ \left[\mathcal{Q}_{\leq \gamma} - \mathbb{I}_t \right] \sum_{l \in \mathcal{L}_t} F_l^t (V_t^Z + \mathcal{P}^Z \bar{U}) \Xi_l ] - \bar{U}_t + \mathcal{P}^Z_t 1_+ \bar{U}_t
\]
\[
+ G_t v_0^t + G_t \bar{u}_0^{Z,t}
\]
\[
= \mathcal{P}^Z_t \left[1_+ \mathcal{Q}_{\leq \gamma} - \mathbb{I}_t \right] \sum_{l \in \mathcal{L}_t} F_l^t (V_t^Z + \mathcal{P}^Z \bar{U}) \Xi_l ] + G_t v_0^t + G_t \bar{u}_0^{Z,t}.
\]
It remains to observe that $1_+ F_l^t (V^Z + \mathcal{P}^Z \bar{U}) = 1_+ F_l^t (\mathcal{U}^Z)$, which readily follows from the identity \eqref{eq:6.17}. \hfill \Box

**Appendix A Additional proofs**

**A.1 Proof of Lemma 3.17**

**Proof of Lemma 3.17** Let $F \in \mathcal{Q}$ and $M \in \mathcal{R}$. Suppose that for $t \in \Sigma_+$, $l = (l, o) \in \mathcal{L}_t$ and $\tau \in \mathcal{T}_{\mathcal{Q}}$ one has $\langle M^* \Xi_l, \tau \rangle \neq 0$. Let $\alpha \in \mathbb{N}^0$ such that $\alpha \notin D(t, \alpha \sqcup l)$. To conclude that $MF \in \mathcal{Q}$ it suffices, by Proposition 3.18, to show that $D^\alpha T^F_t [\tau] = 0$. 

To this end, let us add an additional “driver” element \( \Xi \) and construct the spaces \( \tilde{V} \) and \( \tilde{\mathcal{V}} \) in the identical manner to \( V \) and \( \mathcal{V} \) but instead using the set \( \mathcal{D} \defeq \mathcal{D} \sqcup \{ \Xi \} \) in place of \( \mathcal{D} \). Note that we can canonically identify \( \mathcal{V} \) with a subspace of \( \tilde{\mathcal{V}} \). We also set \( \tilde{\mathcal{Y}}_k[\Xi] \defeq 1 \) for all \( b \in \Xi \).

Let us write \( \alpha \) as a multi-set \( \alpha = \{(t_1, p_1), \ldots, (t_k, p_k)\} \) for some \( k \geq 0 \) and \( (t_j, p_j) \in \emptyset \). Consider the element

\[
\tilde{\tau} \defeq \Xi \hat{\cup}_{(t_1, p_1)}(\Xi \hat{\cup}_{(t_2, p_2)}(\ldots (\Xi \hat{\cup}_{(t_n, p_n)} \tau) \ldots)) \in \tilde{\mathcal{V}}.
\]

Note that in the case \( k = 0 \), one simply has \( \tilde{\tau} = \tau \). By (5.14) we have

\[
D^\alpha \hat{\mathcal{Y}}_k[\tau] = D_{(t_1, p_1)} \ldots D_{(t_n, p_n)} \hat{\mathcal{Y}}_k[\tau] = \hat{\mathcal{Y}}_k[\tilde{\tau}].
\]

Write \( \tilde{\tau} \) as a sum of trees \( \tilde{\tau} = \sum_{i=1}^N c_i \tilde{\tau}_i \) with \( \tilde{\tau}_i \in \tilde{\mathcal{V}} \). Observe that due to the choice \( \hat{\mathcal{Y}}_k[\Xi] = 1 \), for every \( \tilde{\tau}_i \) with an edge whose two adjacent nodes carry the label \( \Xi \), it holds that \( \hat{\mathcal{Y}}_k[\tilde{\tau}_i] = 0 \).

Consider a tree \( \tilde{\tau}_i \) in which every edge has at most one adjacent node with the label \( \Xi \). We may identify \( \tilde{\tau}_i \) with an element \( \tau_i \in \mathcal{V} \) by mapping the label \( \Xi \) to 1. However, by the assumption that the rule \( R \) is complete, that \( \emptyset \not\in D(t, \emptyset \cup \emptyset) \), and that \( (\mathcal{M}_\emptyset \Xi, \tau) \neq 0 \), it necessarily holds that \( J_{(t, 0)}[\tau_i] \not\in T^{\text{ex}} \). Therefore, there exists a non-leaf node in \( J_{(t, 0)}[\tau_i] \) with label \( \Xi \in (\emptyset, \emptyset) \), incoming edge \( t \), and a multi-set of outgoing edges \( \beta \in \mathcal{N}^\emptyset \) with \( \emptyset \not\in D(t, \beta \cup \emptyset) \). Again by Proposition 3.8 it holds that \( D^\beta \hat{F}_1 = 0 \), and thus \( \hat{\mathcal{Y}}_k[\tilde{\tau}_i] = 0 \), which concludes the proof.

\[ \square \]

### A.2 Proof of Lemma 4.3

The key ingredient for establishing the lemma is the following multi-variable generalisation of the Faa di Bruno formula. In order to state this formula we first introduce some more notation.

We fix some choice of a total order “\( < \)” on the set \( \mathbb{N}^{d+1} \) with the property that 0 is the minimal element. Then for each \( r \in \mathbb{N} \) and \( k \in \mathbb{N}^{d+1} \setminus \{0\} \) we define the set

\[
I(r, k) \defeq \left\{(\vec{q}, \vec{m}) \in (\mathbb{N}^{d+1})^r \times (\mathbb{N}^\emptyset \setminus \{0\})^r : 0 < q_1 < q_2 < \cdots < q_r, \sum_{j=1}^r m_j \cdot q_j = k \right\}.
\]

We also set \( I(k) \defeq \bigcup_{r=0}^\infty I(r, k) \). Additionally, for \( (\vec{q}, \vec{m}) \in I(r, k) \) we use the shorthands \( r(\vec{q}, \vec{m}) = r \) and \( m \defeq \sum_{j=1}^r m_j \). Note that \( I(0, k) = \emptyset \) except for the case \( k = 0 \) when \( I(k) = \{(0, 0)\} \) with \( r(0, 0) = 0 \).

We can now state the mentioned Faa Di Bruno formula.

**Lemma A.1** For any \( k \in \mathbb{N}^{d+1} \) and \( F \in \mathcal{P} \) one has

\[
\partial^k F = k! \sum_{(\vec{q}, \vec{m}) \in I(k)} \left[ \prod_{1 \leq j \leq r(\vec{q}, \vec{m}) \atop (t, p) \in \emptyset} \frac{1}{m_j[(t, p)]} \left( \frac{1}{q_j} \bar{\mathcal{Y}}_{(t, p) + q_j} \right)^{m_j[(t, p)]} \right] \cdot D^m F, \quad (A.1)
\]

where \( m_j[(t, p)] \) denotes the \((t, p)\) component of \( m_j \in \mathbb{N}^\emptyset \).
That the above formula really is a “Faa Di Bruno” formula is partially obscured by our notation. One should view the indeterminates \( \{X_{(t,p)}\}_{(t,p) \in \mathbb{N}} \) as representing a family of smooth functions from \( \mathbb{R}^{d+1} \) to \( \mathbb{R} \), namely one fixes smooth functions \( \{u_{i}(z)\}_{i \in \mathbb{N}} \) and then the correspondence is given by \( X_{(t,p)} \mapsto \partial_{z}^{p}u_{t}(z) \) where \( \partial_{z} \) denotes the vector of partial derivatives in the components of \( z \).

Then one has, for \( F \in \mathcal{P} \), \( m \in \mathbb{N}^{0} \), and \( k \in \mathbb{N}^{d+1} \),

\[
F(X) \leftrightarrow F((\partial_{t}^{p}u_{t} : (t, p) \in \mathbb{N})) \tag{A.2}
\]

\[
D^{m}F(X) \leftrightarrow \left( \prod_{(t, p) \in \mathbb{N}} \frac{\partial}{\partial(\partial_{t}^{p}u_{t}(z))} \right) F((\partial_{t}^{p}u_{t}(z) : (t, p) \in \mathbb{N}))
\]

\[
\partial^{k}F(X) \leftrightarrow \partial_{z}^{k}F((\partial_{t}^{p}u_{t}(z) : (t, p) \in \mathbb{N}))
\]

We then compute \( \partial^{k}F \) by manipulation of Taylor series (seen as formal power series). We first expand the \( \partial_{t}^{p}u_{t} \) into Taylor series in \( z \), insert these Taylor series into the one for \( F \) in the variables \( \partial_{t}^{p}u_{t} \), and then read off the coefficient of \( z^{k} \) in the resulting power series.

If one takes the correspondences of (A.2) for granted, then the proof of Lemma A.1 is immediate, for completeness we give a careful proof below. A more combinatorial proof of the formula can be found in [Mao].

**Proof of Lemma A.1** We first claim that it suffices to prove the identity (A.1) for the case where the function \( F \) is actually a polynomial in the variables \( \{X_{(t,p)}\}_{(t,p) \in \mathbb{N}} \). To see this is the case first note that if \( k \in \mathbb{N}^{d+1} \), \( x = (x_{o})_{o \in \mathbb{N}} \in \mathbb{R}^{\mathbb{N}} \) and \( F,G \in \mathcal{P} \) with \( (D^{m}F)(x) = (D^{m}G)(x) \) for every \( m \in \mathbb{N}^{0} \) with \( |m| \leq |k| \) then it follows that \( (\partial^{k}F)(x) = (\partial^{k}G)(x) \).

Now suppose that the formula (A.1) holds whenever \( F \in \mathcal{P} \) is a polynomial of \( X \) and we want to verify it for \( G \in \mathcal{P} \) and \( k \in \mathbb{N}^{d+1} \) at a point \( x \in \mathbb{R}^{\mathbb{N}} \). The desired claim follows by applying the identity (A.1) to the polynomial \( F_{x} \), given by

\[
F_{x}(X) \overset{def}{=} \sum_{m \in \mathbb{N}^{0}} \frac{D^{m}G(x)}{m!} X^{m}.
\]

We turn to proving (A.1) for polynomial \( F \). In the remainder of this proof we define \( z \) and \( w \) to be two vectors of mutually commuting indeterminates \( (z_{0}, \ldots, z_{d}) \), \( (w_{0}, \ldots, w_{d}) \) that will be the variables of our formal power series. Given a formal power series \( \mathcal{A}(z, w) \overset{def}{=} \sum_{j,k \in \mathbb{N}^{d+1}} A_{j,k} z^{j}w^{k} \) we use the notation \([A(z, w); z^{j}w^{k}] = A_{j,k} \). We introduce an \( \mathbb{N} \)-indexed family of power series

\[
X_{(t,p)}(z) \overset{def}{=} \sum_{q \in \mathbb{N}^{d+1}} \frac{z^{q}}{q!} X_{(t,p+q)}.
\]

Then each polynomial \( F(X) \) can be associated to a power series

\[
F(X(z)) = \sum_{m \in \mathbb{N}^{0}} \frac{D^{m}F(X)}{m!} (X(z) - X)^{m}.
\]
For \( k \in \mathbb{N}^{|I|+1} \) we define \( \partial^k F \overset{\text{def}}{=} k![F(\mathcal{X}(z)); z^k] \), by induction one sees that \( \partial^k F = \partial^k F \). For the base cases we clearly have that \( \partial^k = \partial^k \) if \( |k| \leq 1 \). For the inductive step follows observe that for any \( j, k \in \mathbb{N}^{|I|+1} \),
\[
\partial^j \partial^k F = j! k! [F(\mathcal{X}(z + w)); w^j z^k] = (j + k)! [F(\mathcal{X}(z)); z^{k+j}] = \partial^{j+k} F,
\]
where in the first equality we are using that \( F \) is a polynomial and in the second equality we are using the binomial formula.

All that remains is showing that for \( k \neq 0 \) the coefficient \( k![F(\mathcal{X}(z)); z^k] \) is given by the RHS of (A.1). When expanding the RHS of (A.4) the terms that come with a \( z^k \) are indexed by \( I(k) \).

Namely, one chooses an integer \( r > 0 \), and then a collection of powers \( 0 < q_1 < q_2 < \cdots < q_r \in \mathbb{N}^{|I|+1} \) corresponding to the \( q \)'s that one will allow oneself to pick out in (A.3) when expanding \( (\mathcal{X}(z) - \mathcal{X})^m \) for some \( m \). Next, one chooses a tuple \( m_1, \ldots, m_r \in \mathbb{N}^{|I|} \setminus \{0\} \) where \( m_j \) records from which \( (t, p) \in \Theta \) and with what multiplicity one is drawing out powers of \( z^q \). To obtain an overall power of \( z^k \) one has the constraint \( k = \sum_{j=1}^r |m_j| q_j \). The corresponding \( m \in \mathbb{N}^{|I|} \) in the first sum of (A.4) is given by \( m = \sum_{j=1}^r m_j \). The corresponding coefficient of \( z^k \) which is contributed is given by the summand on the RHS of (A.1).

**Proof of Lemma [4.3]** We prove the statement of the lemma by induction over the number of internal nodes of \( \tau \). The base case, when \( \tau \) is a trivial tree, can be proven in the same way as the inductive step so we immediately turn to proving the latter.

Suppose that \( \tau \) is of form (4.5) with \( N \) edges and that the claim has been proved for any \( \tilde{\tau} \in \mathcal{V} \) with fewer than \( N \) edges. Applying Lemma [3.2] for \( Q \) one gets that \( Q^* \tau \) is given by
\[
\Xi_k \sum_{(\tilde{q}, \tilde{m}) \in I(k)} \left( \prod_{1 \leq j \leq r(\tilde{q}, \tilde{m}), (l, p) \in \Theta} \frac{1}{m_j[(t, p)]!(X_{(l+p)}^{t+q_j})^{m_j[(t, p)]} q_j!} \right) \left( \prod_{w=1}^n \mathcal{Y}_{w}^{F}[\tau_{w}] \right).
\]

By applying \( \tilde{\mathcal{Y}}_{[\cdot]} \) to the quantity above and applying the inductive hypothesis we see that the RHS of (4.4) is given by
\[
\sum_{(\tilde{q}, \tilde{m}) \in I(k)} \left( \prod_{1 \leq j \leq r(\tilde{q}, \tilde{m}), (l, p) \in \Theta} \frac{1}{m_j[(t, q)]!(X_{(l+p)}^{t+q_j})^{m_j[(t, p)]} q_j!} \right) \left( \prod_{w=1}^n \mathcal{Y}_{w}^{F}[\tau_{w}] \right)
\cdot \left( D_m \left( \prod_{w=1}^n D_{(l, w-p, w)} \right) \right). \quad (A.5)
\]
The desired result follows by applying Lemma (A.1).

**A.3 Proof of Proposition 5.12**
The proof of Proposition 5.12 relies on the next two lemmas. We prove them by invoking a more general co-interaction property described in [BHZ16, Thm 3.22].
Lemma A.2 On $\mathcal{T}^\text{ex}$, it holds that for $(t, p) \in \mathcal{O}$

$$\mathcal{M}^{(13)(2)(4)}(\Delta^+ \otimes \Delta^-)(\hat{\cdot})_{(t,p)} = (\text{id} \otimes \hat{\cdot})_{(t,p)} \Delta^-_{\text{ex}}.$$  

Lemma A.3 On $\mathcal{T}^\text{ex}$, it holds that for any $i \in \{0, \ldots, d\}$,

$$\Delta^-_{\text{ex}} i^* = (\text{id} \otimes i^*) \Delta^-_{\text{ex}}.$$ 

Before proving these lemmas, we recall some notations and the definition of $\Delta^-_{\text{ex}}$. Let $\mathcal{T}^\text{ex}$ be the free commutative algebra generated by $\mathcal{T}^\text{ex}$. Then we set $\mathcal{T}^\text{ex} = \mathcal{T}^\text{ex}/\mathcal{J}_+$ where $\mathcal{J}_+$ is the ideal of $\mathcal{T}^\text{ex}$ generated by $\{\tau \in \mathcal{T}^\text{ex} : |\tau|_e \geq 0\}$. The map $\Delta^-_{\text{ex}} : \mathcal{T}^\text{ex} \rightarrow \mathcal{T}^\text{ex} \otimes \mathcal{T}^\text{ex}$ is given for $T^{n,\varnothing}_t \in \mathcal{T}^\text{ex}$ by:

$$\Delta^-_{\text{ex}} T^{n,\varnothing}_t = \sum_{A \subseteq T} \sum_{\varepsilon_A : N_A \rightarrow N^{d+1}} \frac{1}{\varepsilon_A!} \left( \binom{n}{n_A} \right) (A, n_A + \pi \varepsilon_A, \sigma[N_A, \pi E_A])$$

$$\otimes (\mathcal{R}_A T - [n - n_A] A, \sigma(A) + [n_A - \pi \varepsilon_A] A, \varepsilon + \varepsilon_A),$$

where

- For $C \subseteq D$ and $f : D \rightarrow \mathbb{N}^d$, we denote by $f|C$ the restriction of $f$ to $C$.
- The first sum runs over all subgraphs $A$ of $T$ ($A$ may be empty). The second sum runs over all $n_A : N_A \rightarrow \mathbb{N}^{d+1}$ and $\varepsilon_A : \partial(A, T) \rightarrow \mathbb{N}^{d+1}$ where $\partial(A, F)$ denotes the edges in $E_T \setminus E_A$ that are adjacent to $N_A$.
- We write $\mathcal{R}_A T$ for the tree obtained by contracting the connected components of $A$. This gives an action on the decorations in the sense that for $f : N_T \rightarrow \mathbb{N}^{d+1}$ such that $A \subseteq T$ one has: $[f]_A(x) = \sum_{x \sim_A y} f(y)$ where $x$ is an equivalence class of $\sim_A$ and $x \sim_A y$ means that $x$ and $y$ are connected in $A$. Moreover, the map $\sigma(A)$ is defined on $x$ by:

$$\sigma(A)(x) = \sum_{y \sim_A x} \sigma(y) + \sum_{e \in E_A} (t(e) - e(e)).$$

- For $f : E_T \rightarrow \mathbb{N}^{d+1}$, we set for every $x \in N_T$, $(\pi f)(x) = \sum_{e = (x, y) \in E_T} f(x)$. Then one can turn this map into a coproduct $\Delta^-_{\text{ex}} : \mathcal{T}^\text{ex} \rightarrow \mathcal{T}^\text{ex} \otimes \mathcal{T}^\text{ex}$ and obtain a Hopf algebra for $\mathcal{T}^\text{ex}$ endowed with this coproduct and the forest product, see [BH16, Prop. 5.35]. Any $M_\ell \in \mathfrak{N}$ is described by an element $\ell$ of the character group $\mathcal{G}_{\text{ex}}^\ast$ associated to this Hopf algebra:

$$M_\ell = (\ell \otimes \text{id}) \Delta^-_{\text{ex}},$$

where $\Delta^-_{\text{ex}}$ is the co-action defined in (A.6). Before stating the main co-interaction, we need to recall the definition of another map $\Delta_2$ given in [BH16]. Let $\mathcal{T}^\text{ex}_+$ denote the linear span of $\mathcal{T}^\text{ex}_+$, the coloured trees $(T, \ell)_\ell^{\text{ex}}$ such that $T^{-1}(\{2\}) = \sigma_T$ and $\sigma(\sigma_T) = 0$. If we consider that a vertex $x$ has the colour 1 when $\sigma(x) \neq 0$ then we can use lighter notations avoiding the notion of a coloured tree and consider that
\( \hat{T} \in \{0, 2\} \). Hence, elements of \( \hat{T}_+^{\text{ex}} \) are denoted by \( (T, 2)^{n, \varnothing}_r \) and those of \( \mathcal{T}_+^{\text{ex}} \) are denoted by \( T_t^{n, \varnothing} = (T, 0)^{n, \varnothing}_r \). Then the map \( \hat{\Delta}_2 : \hat{\mathcal{T}}^{\text{ex}} \rightarrow \hat{\mathcal{T}}^{\text{ex}} \otimes \hat{\mathcal{T}}_+^{\text{ex}} \) is given for \( T_t^{n, \varnothing} \in \hat{\mathcal{T}}_+^{\text{ex}} \) by:

\[
\hat{\Delta}_2 T_t^{n, \varnothing} = \sum_{A \in \mathcal{T}_r} \prod_{e \in n} \frac{1}{e_A!} \left( \mathcal{M}^{(13)(2)(4)} \left( \hat{\Delta}_-^e \otimes \hat{\Delta}_-^e \right) \Delta_2 = (\text{id} \otimes \Delta_2) \Delta_2^e . \right.
\]

This identity is a consequence of the co-interaction given in [BHZ16 Thm 3.22]:

\[
\mathcal{M}^{(13)(2)(4)} (\Delta_1 \otimes \Delta_2) \Delta_2 = (\text{id} \otimes \Delta_2) \Delta_1 .
\]

We apply \( p_+^{\text{ex}} \otimes \text{id} \otimes \text{id} \) to \( A \) in order to obtain \( A \) where \( p_+^{\text{ex}} \) is the projection onto the forest composed of trees with negative degree. The main idea of the following proofs is to rewrite \( \hat{\mathcal{A}}_{(l,p)} \) and \( \hat{\mathcal{T}}_{i} \) in terms of \( \hat{\Delta}_2 \) and some projections which behave well with \( \Delta_2^e \).

**Proof of Lemma** \[\text{A.2}\] For \( \hat{\Delta}_{(l,p)} \) from Definition \[\text{S.5}\] we have the identity

\[
\hat{\Delta}_{(l,p)} = \mathcal{M}^{(2)(1)} \left( \text{id} \otimes \mathcal{R}_2 \circ p_{(l,p)} \circ \Pi_{p_+^{\text{ex}}} \right) \Delta_2
\]

where

- \( \mathcal{M}^{(2)(1)} (\tau_1 \otimes \tau_2) \overset{\text{def}}{=} (\tau_2 \otimes \tau_1) \),
- \( \Pi_{p_+^{\text{ex}}} : \hat{\mathcal{T}}^{\text{ex}}_+ \rightarrow \hat{\mathcal{T}}_+^{\text{ex}} \) is the projection onto \( \hat{\mathcal{T}}_+^{\text{ex}} \),
- \( p_{(l,p)} : \hat{\mathcal{T}}_+^{\text{ex}} \rightarrow \hat{\mathcal{T}}_+^{\text{ex}} \) is the projection onto planted trees with the root edge decorated by \( (t, k) \) for some \( k \leq p \),
- \( \mathcal{R}_2 : \hat{\mathcal{T}}_+^{\text{ex}} \rightarrow \hat{\mathcal{T}}^{\text{ex}}_+ \) acts by removing the edge incident to the root and the color blue at the root.

Then it is easy to show that the following identities hold:

\[
(\text{id} \otimes \mathcal{R}_2) \Delta_2^e = \Delta_2^e \mathcal{R}_2, \quad (\text{id} \otimes p_{(l,p)}) \Delta_2^e = \Delta_2^e p_{(l,p)} \quad \text{on} \quad \hat{\mathcal{T}}_+^{\text{ex}},
\]

\[
\left( \text{id} \otimes \Pi_{p_+^{\text{ex}}} \right) \Delta_2^e = \Delta_2^e \Pi_{p_+^{\text{ex}}} \quad \text{on} \quad \hat{\mathcal{T}}_+^{\text{ex}}.
\]

Indeed, the previous projections are linked to the form of the tree at the root. The root is coloured in blue and therefore cannot be touch by \( \Delta_2^e \). Then by using these identities, we have

\[
\mathcal{M}^{(13)(2)(4)} (\Delta_2^e \otimes \Delta_2^e) \hat{\mathcal{A}}_{(l,p)}
\]
\[ M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \cdot M^{(2)(1)}(\text{id} \otimes \mathcal{R}_2 \circ p_{(t,p)} \circ \Pi_{\hat{p}^*}) \Delta_2 = (\text{id} \otimes M^{(2)(1)}) M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \left( \text{id} \otimes \mathcal{R}_2 \circ p_{(t,p)} \circ \Pi_{\hat{p}^*} \right) \Delta_2 \]
\[ = (\text{id} \otimes M^{(2)(1)}) M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \left( \text{id} \otimes \mathcal{R}_2 \circ p_{(t,p)} \circ \Pi_{\hat{p}^*} \right) \Delta_2 \]
\[ = (\text{id} \otimes M^{(2)(1)}) M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \left( \text{id} \otimes \mathcal{R}_2 \circ p_{(t,p)} \circ \Pi_{\hat{p}^*} \right) \Delta_2 \]
\[ = \left( \text{id} \otimes M^{(2)(1)} \left( \text{id} \otimes \mathcal{R}_2 \circ p_{(t,p)} \circ \Pi_{\hat{p}^*} \right) \right) \left( \text{id} \otimes \Delta_2 \right) \Delta_{\text{ex}} \]
\[ = (\text{id} \otimes \hat{\wedge}_{o^*}) \Delta_{\text{ex}}. \]

\[ \square \]

**Proof Lemma A.3** The map \( \hat{\iota}_i \) from Definition 5.7 can be rewritten as
\[ \hat{\iota}_i = M^{(1)}(\text{id} \otimes p_{X_i}) \Delta_2 \]
where \( M^{(1)}(\tau_1 \otimes \tau_2) = \tau_1 \) and \( p_{X_i} : \hat{G}^+_{\text{ex}} \rightarrow \hat{G}^+_{\text{ex}} \) is the projection on the tree composed of one node coloured in blue corresponding to \( X_i \). One has \((\text{id} \otimes p_{X_i}) \Delta_{\text{ex}} = p_{X_i} \) and by using this identity it follows that
\[ \left( \text{id} \otimes M^{(1)} \left( \text{id} \otimes p_{X_i} \right) \right) M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \Delta_2 \]
\[ = (\text{id} \otimes M^{(1)} \left( \text{id} \otimes p_{X_i} \right) \Delta_{\text{ex}} \otimes \left( \text{id} \otimes p_{X_i} \right) \Delta_{\text{ex}}) \Delta_2 \]
\[ = (\text{id} \otimes M^{(1)}) \left( \Delta_{\text{ex}} \otimes p_{X_i} \right) \Delta_2 \]
\[ = \Delta_{\text{ex}} M^{(1)}(\text{id} \otimes p_{X_i}) \Delta_2 = \Delta_{\text{ex}} \hat{\iota}_i \]

On the other hand, we obtain:
\[ \left( \text{id} \otimes M^{(1)} \left( \text{id} \otimes p_{X_i} \right) \right) (\text{id} \otimes \Delta_2) \Delta_{\text{ex}} = \left( \text{id} \otimes \hat{\iota}_i \right) \Delta_{\text{ex}}. \]

\[ \square \]

**Remark A.4** Lemmas A.2 and A.3 can be proven without the use of the strong co-interaction obtained in [BHZ16, Thm. 3.22]. The difficult part of the proof is taking care of the binomial coefficients and one can handle this by using the Chu-Vandermonde identity in a more elementary way than in the proof of [BHZ16, Thm. 3.22]. Lemma A.3, for example, only needs the identity \( a \binom{a+b}{b} = (a-b) \binom{a}{b} \) for \( a, b \in \mathbb{N} \).

**Proof Proposition 5.12** Let \( \ell \in G^+ \) and set \( M_\ell = (\ell \otimes \text{id}) \Delta_{\text{ex}} \in \mathcal{R} \). Lemma A.3 implies that any \( i \in \{0, \ldots, d\} \)
\[ M_\ell \hat{\iota}_i = (\ell \otimes \text{id}) \Delta_{\text{ex}} \hat{\iota}_i = (\ell \otimes \hat{\iota}_i) \Delta_{\text{ex}} = \hat{\iota}_i M_\ell, \]
from which (5.16) follows. Turning to (5.17), for \( o \in \mathcal{O} \) one has, by Lemma A.2
\[ \hat{\wedge}_o M_\ell = (\ell \otimes \hat{\wedge}_o) \Delta_{\text{ex}} \]
\[ = (\ell \otimes \text{id} \otimes \text{id}) M^{(13)(2)(4)}(\Delta_{\text{ex}} \otimes \Delta_{\text{ex}}) \hat{\wedge}_o \]
\[ = (\ell \otimes \text{id} \otimes \text{id}) \left( (\ell \otimes \text{id}) \Delta_{\text{ex}} \otimes (\ell \otimes \text{id}) \Delta_{\text{ex}} \right) \hat{\wedge}_o = (M_\ell \otimes M_\ell) \hat{\wedge}_o. \]

Passing to the adjoint and using Corollary 5.11 concludes the proof.

\[ \square \]
A.4 Proof of Proposition 5.14

Proof of Proposition 5.14 Our proof follows the one given in [CL01] for rooted trees without decorations on the grafting operators. We first consider decorated variables \(x^{(k)}, k \in \mathbb{N}^{d+1}\), and decorated brackets \((\cdot)(l,p)\). Let \(\mathcal{F}^{ex}(n)\) the vector space given by parenthesised product on these variables indexed by \(\{1, \ldots, n\}\), using the previous decorated brackets. For example, a basis for \(\mathcal{F}^{ex}(2)\) is given by:

\[
(x_1^{(k_1)} x_2^{(k_2)})(l,p), \quad (x_2^{(k_2)} x_1^{(k_1)})(l,p), \quad (l,p) \in \emptyset, \quad k_i \in \mathbb{N}^{d+1}.
\]

We set \(\mathcal{P}\mathcal{L}^{ex} = \mathcal{F}^{ex}/(R)\) where \(\mathcal{F}^{ex} = (\mathcal{F}^{ex}(n))_{n \geq 1}\) and the equivalence relation \(R\) is generated by the relations

\[
\begin{align*}
\tau(r) & = (x_1^{(k_1)} x_2^{(k_2)} h_{(l_1,p_1)}^{(k_3)} h_{(l_2,p_2)}^{(k_4)})_{(l_1,p_1)} - (x_1^{(k_1)} x_2^{(k_2)} h_{(l_1,p_1)}^{(k_3)} h_{(l_2,p_2)}^{(k_4)})_{(l_1,p_1)} \\
& \quad - (x_2^{(k_2)} x_1^{(k_1)} h_{(l_2,p_2)}^{(k_3)} h_{(l_1,p_1)}^{(k_4)})_{(l_1,p_1)} + (x_2^{(k_2)} x_1^{(k_1)} h_{(l_2,p_2)}^{(k_3)} h_{(l_1,p_1)}^{(k_4)})_{(l_1,p_1)}.
\end{align*}
\]

Let \(\mathcal{R}\mathcal{T}^{ex}(n)\) be the linear span of trees with edge decorations in \(\emptyset\) and having their nodes labelled by \(\{1, \ldots, n\}\). Moreover, they do not have drivers. For \((l,p) \in \emptyset\), we define the grafting operator \(\hat{\varphi}_{(l,p)}\) as a linear map from \(\mathcal{R}\mathcal{T}^{ex}(m) \otimes \mathcal{R}\mathcal{T}^{ex}(n)\) into \(\mathcal{R}\mathcal{T}^{ex}(n + m)\) by

\[
\tau \hat{\varphi}_{(l,p)} \tau = \sum_{\ell} \left( \begin{array}{c} k_r \\ \ell \end{array} \right) \cdot \sum_{j \in J} \mathcal{J}_{(l,p-\ell)}[\tau] \left( \prod_{j \in J} \mathcal{J}_{\ell_j}[\tau_j] \right) + \sum_{j \in J} \mathcal{J}_{\ell_j}[\tau \hat{\varphi}_{(l,p)} \tau_j],
\]

where \(\cdot^{k_r}\) is the rooted tree composed of a single node labelled by \(r\) and decorated by \(k_r\). Note that the expression of this grafting operator is essentially identical to the one given in Remark 5.6, we commit here an abuse notation by identifying the two operators. The grafting operator \(\hat{\varphi}_{(l,p)}\) satisfies a pre-Lie type identity:

\[
(t_1 \hat{\varphi}_{(l_1,p_1)} t_2) \hat{\varphi}_{(l_2,p_2)} t_3 - t_1 \hat{\varphi}_{(l_1,p_1)} (t_2 \hat{\varphi}_{(l_2,p_2)} t_3) = (t_2 \hat{\varphi}_{(l_2,p_2)} t_1) \hat{\varphi}_{(l_1,p_1)} t_3 - t_2 \hat{\varphi}_{(l_2,p_2)} (t_1 \hat{\varphi}_{(l_1,p_1)} t_3).
\]

We define a morphism \(\Phi : \mathcal{P}\mathcal{L}^{ex} \to \mathcal{R}\mathcal{T}^{ex}\) for the concatenation \(w = (uv)_{(l,p)}\) of two words \(u\) and \(v\) by setting

\[
\Phi(x_i^{(k_i)}) \overset{def}{=} k_i, \quad \Phi(uv)_{(l,p)} \overset{def}{=} \Phi(u) \hat{\varphi}_{(l,p)} \Phi(v).
\]

The identity (A.9) proves that \(\Phi(r) = 0\), so that this is well-defined.

We want to construct an inverse \(\Psi\) of \(\Phi\). Let us fix a finite set \(I\) and write \(\mathcal{R}\mathcal{T}^{ex}(I)\) for the decorated trees of \(\mathcal{R}\mathcal{T}^{ex}\) labelled with \(I\). We consider \(\Phi_I : \mathcal{P}\mathcal{L}^{ex}(I) \to \mathcal{R}\mathcal{T}^{ex}(I)\) the extension of \(\Phi\). We want to define a map \(\Psi_I : \mathcal{R}\mathcal{T}^{ex}(I) \to \mathcal{P}\mathcal{L}^{ex}(I)\) such that \(\Psi_I \Phi_I = \text{id}\) and \(\Phi_I \Psi_I = \text{id}\). We proceed by induction on the cardinal \(|I|\) of \(I\). The initialisation with only one element in \(I\) is straightforward.
We define the map $\Psi_1$ by induction on $N$. If $N = 1$, observe that
\[
T = \bullet_{(\ell_1, p_1)}^{(k_r)} J_{(\ell_1, p_1)}[\tau_1] = \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} (\tau \overset{\ell_1}{\wedge}(\ell, p_1 - \ell) \bullet_{(\ell, p_1)}^{(k_r - \ell)}), \quad (A.10)
\]
with the convention that the terms with $k_r - \ell$ are zero when $k_r = 0$. Then we set $\Psi_1(T) = \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} \binom{x_1^{(k_r - \ell)} \Psi_1(\tau_1)}{(\ell, p_1 - \ell)}$, where we note that $\Psi_1(\tau_1)$ is well-defined due to our induction hypothesis on $|I|$. It is then immediate to verify that $\Phi_1 \Psi_1(T) = T$. If $N \geq 2$, observe that
\[
T = \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} \tau_1 \overset{\ell_1}{\wedge}(\ell_1, p_1 - \ell) \bullet_{(\ell_1, p_1)}^{(k_r - \ell)} \prod_{i=2}^N J_{(\ell_i, p_i)}[\tau_i]
- \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} \sum_{j=2}^N \bullet_{(\ell_1, p_1)}^{(k_r - \ell)} J_{(\ell_1, p_1)}[\tau_1 \overset{\ell_1}{\wedge}(\ell_1, p_1 - \ell) \tau_j] \prod_{i \neq j} J_{(\ell_i, p_i)}[\tau_i].
\]
Note that intuitively, this represents an “ungrafting” of $\tau_1$ from the root of $T$. Then we define $\Psi_1(T)$ by
\[
\Psi_1(T) = \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} \left( \Psi_1(\tau_1) \Psi_1 \left( \bullet_{(\ell_1, p_1)}^{(k_r - \ell)} \prod_{i=2}^N J_{(\ell_i, p_i)}[\tau_i] \right) \right)_{(\ell_1, p_1 - \ell)}
- \sum_\ell (-1)^{|\ell|} \binom{k_r}{\ell} \sum_{j=2}^N \Psi_1 \left( \bullet_{(\ell_1, p_1)}^{(k_r - \ell)} J_{(\ell_1, p_1)}[\tau_1 \overset{\ell_1}{\wedge}(\ell_1, p_1 - \ell) \tau_j] \prod_{i \neq j} J_{(\ell_i, p_i)}[\tau_i] \right).
\]
One can then verify that $\Phi_1 \Psi_1(T) = T$ as desired. Since the tree $T$ is invariant under permutation of the $T_i = J_{(\ell_i, p_i)}[\tau_i]$, we need to check that the definition of $\Psi_1(T)$ does not depend on the subtree we ungraft from the root of $T$ (in the above, this was taken as $\tau_1$). We proceed by induction on $N$ and we prove that the order of ungrafting $\tau_1$ and $\tau_2$ does not matter in the definition of $\Psi_1(T)$. The proof follows in exactly the same way as in [CL01] but we have longer expressions because of the identity (A.10). We omit the details but note that the relations $R$, the symmetries, and the pre-Lie identity (A.3) provide all the necessary ingredients for the verification.

It remains to prove that one has $\Psi \Phi = \text{id}$. We show by induction on $N$ that
\[
\Psi(T' \overset{\ell_1}{\wedge}(p, p) T) = (\Psi(T'))(T)_{(\ell_1, p)}.
\]
If we consider a word $w$ in $\mathcal{P}\mathcal{L}^{\text{ex}}$ then $w = (uw)_{b,b}$ and we get:

$$\Psi \Phi(w) = \Psi((\Phi(u) \hat{\gamma}_{(l,p)} \Phi(v))) = (\Psi(\Phi(u) \Psi(\Phi(v))).$$

We conclude by applying the induction hypothesis on $u$ and $v$. We obtain Proposition \[5.14\] by substituting the indexed nodes by the drivers $\Xi_b$, $l \in \mathcal{D}$. \hfill \Box

### A.5 Proof of Theorem 2.13

**Proof of Theorem 2.13** Given $F \in \mathbb{T}$, we define $F \in \hat{Q}$ as follows. For any if $t \in \mathcal{L}_+$, if $l \in \mathcal{D}_t$ is not of the form $(\xi, 0)$ or $(b, 0, 0)$ for some $b \in \mathbb{L}_-$ then we set $F^b_t \triangleq 0$. We then set $F^t_0 \triangleq F^0_0$ and $F^t_{(b,0,0)} = F^b_t$.

We now construct a corresponding rule $\hat{R}$. If $t \in \mathcal{L}_-$ we set $\hat{R}(t) = \emptyset$. If $t \in L_+$ then writing expanding for each $b \in \mathbb{L}_-$ as in (2.3)

$$F^t_b = F^b_j \left( \mathcal{X} \right) = \sum_{j=1}^{m_{i,b}} F^b_j \left( \mathcal{X} \right) \mathcal{L}^{\alpha_j,b} \left( \mathcal{X} \right),$$

we set

$$\hat{R}(t) \triangleq \left( \bigcup_{b \in \mathbb{L}_-} \left\{ \alpha \sqcup \beta \sqcup ((b, 0)) : \alpha \sqcup \beta \in N_{b}^{0+} \right\} \right) \cup N_{b}^{0+}.$$ 

Note that $\hat{R}$ is normal and subcritical with respect to reg. By \[BH16\] Prop. 5.20 one can extend $\hat{R}$ to a complete rule $\hat{R}$ which is again subcritical with respect to reg. Finally, it is straightforward to verify that $\hat{R}$ satisfies Assumption 3.3 and that $F$ obeys $\hat{R}$. We define as in Section 3 and \[BH16\] Sec. 5 a regularity structure, space of models, and renormalisation group corresponding to the rule $R$.

Let $Z^{(b,c)}$ be the random model obtained by taking the BPHZ lift of the noise $\xi^{(b,c)} \triangleq (\xi^{(b,c)}_{(l,p)})_{l \in \mathcal{L}_-}$. Thanks to the assumptions of Theorem 2.13 we can apply \[CH16\] Thm. 2.15 which states that there exists a random element $Z_{\text{wru}}^0$ of $\mathcal{M}_0$, independent of our choice of mollifier $\varrho$, such that the random models $Z^{(b,c)}$ converge in probability to $Z_{\text{wru}}$ in the topology of $\mathcal{M}_0$ as $\varepsilon \downarrow 0$.

By stationarity it is clear that the models $Z^{(b,c)}_{\text{wru}}$, $Z_{\text{wru}}$ belong to $\mathcal{M}_{0,1}$ almost surely and moreover the convergence of statement of \[CH16\] Thm. 2.15 also implies that $Z^{(b,c)}_{\text{wru}}$ converge to $Z_{\text{wru}}$ in the topology of $\mathcal{M}_{0,1}$ as $\varepsilon \downarrow 0$.

Therefore, by Proposition 6.18 the modelled distributions $\mathcal{P}Z^{(b,c)}_{\text{wru}} \hat{U}$ are well-defined elements of $\mathcal{Y}_{0}^{c,r}$.

We define

$$S^{-}_{b,c}(\zeta) \triangleq \mathcal{R}^{(b,c)}_{\text{wru}} \mathcal{P}Z^{(b,c)}_{\text{wru}} \hat{U}$$

and

$$S^{+}_{b,c}(\zeta, \psi) \triangleq \mathcal{R}^{(b,c)}_{\text{wru}} V Z^{(b,c)}_{\text{wru}} (\psi), \quad (A.11)$$

where $\psi \in C^{\text{neg}}$ and $V^*(v_0)$ is the solution of the fixed point problem (6.16) started at time $s = 0$ with initial data $v_0 \in C^{\text{neg}}$. 

We also define
\[ S_{\varphi,\varepsilon}(\zeta, \psi) \equiv \mathcal{R}^G_{\text{univ}} \mathcal{T}^G_{\text{univ}} (\psi - S^-_e(\zeta)0)) , \]
where \( \mathcal{T}^G_{\text{univ}}(v_0) \) is defined as in (6.17). The identity (6.17) is then an immediate consequence of (6.17) and the definitions we chose above.

By Proposition 6.18, \( S^-_e \) converges in probability, as \( \varepsilon \downarrow 0 \), to \( S^- \equiv \mathcal{R}_\text{univ} \mathcal{Z}_{\text{univ}} \hat{U} \) in the topology of \( \mathcal{C}^{\text{reg}} \). Theorem 6.21 implies that \( S^+_e \) converges in probability, as \( \varepsilon \downarrow 0 \), pointwise in its \( \mathcal{C}^{\text{reg}} \) argument, and in the topology of \( \mathcal{C}_e \), to \( S^+ \equiv \mathcal{R}_\text{univ} \mathcal{Z}_{\text{univ}} \mathcal{U} \). This finishes the proof of the convergence of the various solution maps to a limit which is independent of \( \varphi \). What remains to be verified is that our definition of \( S_{\varphi,\varepsilon} \) given here coincides with the earlier definition (1.15).

By Proposition 6.22, \( \mathcal{T}^G_{\text{univ}}(v_0) \) satisfies the fixed point problem (6.18) - when written in differential form the initial data is given by \( v_0 + \hat{u}_0 \mathcal{Z}^{\text{reg},e} \). Also recall that by definition \( \hat{u}_0 \mathcal{Z}^{\text{reg},e} \) is the canonical lift of \( \hat{u}_0 \) of \( \mathcal{U} \).

We fix initial data \( \psi \in \mathcal{C}^{\text{reg}} \) and set \( \hat{\varphi}(\varphi,e) \equiv S_{\varphi,\varepsilon}(\zeta, \psi) \). By combining the observations of the previous paragraph with Theorem 6.7, it follows that for every \( \varepsilon > 0 \) we have that \( \hat{\varphi}(\varphi,e) \) is a local solution to the system of equations
\[ \hat{\varphi}_t = G_t * \left[ 1 + \sum_{(i,o) \in \mathcal{D}_1} (M_{\text{univ}}(\psi, \zeta))_i (\hat{\varphi}(\varphi,e)_i) + G_t \psi_t, \ t \in \mathbb{L}_+ . \right. \] (A.12)

Here \( M_{\text{univ}}(\psi, \zeta) \) is defined via \( M_{\text{univ}}(\psi, \zeta) \equiv (\ell_{\text{univ}}(\psi, \zeta) \otimes \text{id})^N \), where \( \ell_{\text{univ}}(\psi, \zeta) \equiv E(\Pi(\psi, \zeta) A_{\	ext{ex}})(0) \) and \( \Pi(\psi, \zeta) \) is the canonical lift of \( \Pi(e) = \mathcal{D}_{\text{univ}} \) defined in [BHZ10]. In particular, \( M_{\text{univ}}(\psi, \zeta) \) is a deterministic element of \( \mathcal{R} \) such that \( M_{\text{univ}}(\psi, \zeta) \mathcal{Z}_{\text{univ}} = \mathcal{Z}_{\text{univ}} \).

We now compute \( M_{\text{univ}}(\psi, \zeta) F \). Fix \( t \in \mathbb{L}_+ \). For any \( M \in \mathcal{R} \) and \( (i,o) \in \mathcal{D}_1 \) with \( i \neq j \), we have by the first assumption of (2.18) that \( M(\Xi_{(i,o)}) = \Xi_{(i,o)} \) and consequently, by Definition 3.11, \( (MF)_{(i,o)} = F_{(i,o)} \). Also recall that one always has \( M(\Xi_{(i,o)}) = \Xi_{(i,o)} \). It follows that
\[ \sum_{(i,o) \in \mathcal{D}_1} (M_{\text{univ}}(\psi, \zeta))_i (\hat{\varphi}(\varphi,e)_i) = \sum_{(i,o) \in \mathbb{L}_+} F_t(i,o) \hat{\varphi}(\varphi,e)_i + \sum_{(i,o) \in \mathbb{L}_+} \mathcal{Y}_t^F [ (MF)_{(i,o)}(\hat{\varphi}(\varphi,e)_i) \right) .
\]

Again, by using the first condition of (2.18), we have that
\[ \sum_{(i,o) \in \mathcal{D}_1} \mathcal{Y}_t^F [ (M_{\text{univ}}(\psi, \zeta))_i (\hat{\varphi}(\varphi,e)_i) = \sum_{\tau \in \mathcal{T}_e} \mathcal{Y}_t^F [ \tau(\hat{\varphi}(\varphi,e)) \right) .
\]

It follows that the system (A.12) is the same as the system given in Theorem 2.13 if we set \( c_{e}(T^m) \equiv \ell_{\text{univ}}(T^m) \) for each \( t \in \mathbb{L}_+ \) and \( T^m \in \mathcal{S}_e[F] \), where we are using the natural identification of \( \bigcup_{e \in \mathbb{E}_e} \mathcal{S}_e[F] \) with the trees generating \( \mathcal{T}_e \) (here we are using the notation of [BHZ10]).
## Appendix B  Symbolic index

In this appendix, we collect the most used symbols of the article, together with their meaning and the page where they were first introduced.
