ABSTRACT

Background: Decreases in circulating neutrophils (polymorphonuclear leukocytes, PMNs) have been reported in patients treated with the anti-interleukin-6 receptor (IL-6R) antibody tocilizumab (TCZ); the mechanism for this is unclear. We hypothesize that TCZ reduces circulating neutrophils by affecting margination and / or bone marrow trafficking without affecting neutrophil function or apoptosis.

Materials and methods: 18 healthy subjects were randomized to single intravenous dose of TCZ 8 mg/kg (n = 12) or placebo (n = 6) on day 0. On day 4, each subject had autologous indium-111-labeled neutrophils re-injected, and their kinetics quantified with longitudinal profiling in a whole body gamma-counter. TCZ-treated subjects were divided into two groups according to the extent of reduction in neutrophil count.

Results: Mean day 4 neutrophil counts, as % baseline, were 101.9%, 68.3% and 44.2% in the placebo, TCZ-PMN-‘high’ and TCZ-PMN-‘low’ groups, respectively ($p < 0.001$). Following TCZ, neutrophil function, activation and apoptosis *ex vivo* were all unaffected. *In vivo*, there were no differences in early blood recovery or margination to liver / spleen and bone marrow; however, later neutrophil re-distribution to bone marrow was markedly reduced in the TCZ-PMN-low group (peak pelvic count as % day 4 count on: day 5, 188% placebo vs 127% TCZ-PMN-low, $p < 0.001$; day 10, 180% placebo vs 132% TCZ-PMN-low, $p < 0.01$), with a trend towards higher liver / spleen neutrophil retention.

Conclusions: We have demonstrated for the first time in humans that IL-6R blockade affects neutrophil trafficking to the bone marrow without influencing neutrophil functional capacity.

Key words: neutrophil; interleukin-6; tocilizumab; trafficking

INTRODUCTION

Interleukin-6 (IL-6) is a pleiotropic cytokine with a central role in the pathogenesis of a number of inflammatory and autoimmune disorders [1]. Neutrophils (polymorphonuclear leukocytes, PMNs) are involved in many inflammatory diseases, in part through the release of cytokines and chemokines, and through antigen presentation [2]. Activated neutrophils are a source of soluble interleukin-6 receptor (sIL-6R), initiating 'trans-signaling' in cell types that do not express membrane-bound IL-6R (mIL-6R), thus driving chronic inflammation [3-5].

Tocilizumab (TCZ), a humanized monoclonal antibody against both forms of the IL-6R, is licensed for the treatment of rheumatoid arthritis, systemic juvenile idiopathic arthritis and polyarticular juvenile idiopathic arthritis [6-8]. Decreases in circulating neutrophil levels have been reported after initiation of TCZ in clinical trials. Despite this, the rate of serious infections is low (4.7 per 100 patient-years) [9] and no temporal association has been described between decreased neutrophil counts and the occurrence of such infections [6-10].

Data from animal studies on the effects of IL-6 on neutrophil function have, to date, been inconsistent. IL-6 administration in rabbits results in reduced expression of surface CD62L on circulating and bone marrow neutrophils [11]. IL-6 administration in monkeys, however, results in reduced expression of CD162 whilst CD11b and CD62L expression is unchanged; this process is inhibited by TCZ [12]. In humans, *in vitro* exposure of healthy neutrophils to IL-6 does not affect neutrophil survival or functional capacity [13], although additional lipopolysaccharide (LPS) stimulation following TCZ exposure *in vitro* has been reported to result in differences in oxidative burst and phagocytic capacity under hypoxic conditions

1
2
3 [14]. Studies on neutrophils isolated from patients with rheumatoid arthritis 28 days after
4 administration of TCZ, however, show no effect on neutrophil function or apoptosis [13].
5
6
7
8
9

10 Administration of recombinant human IL-6 in rats [15] and rabbits [16] results in a biphasic
11 blood neutrophilia, with an early peak resulting from leukocyte mobilization from the
12 intravascular marginated pool, and a late peak due to neutrophil release from the post-mitotic
13 bone marrow pool. IL-6 contributes to granulopoiesis in granulocyte colony-stimulating
14 factor (G-CSF)- and granulocyte-macrophage colony-stimulating factor (GM-CSF)-deficient
15 mice [17]. In humans, strenuous exercise similarly causes a biphasic neutrophilia [18] that
16 has been shown to correlate with an increase in serum IL-6 [19], although this correlation has
17 not been replicated in all studies [20].

31

32 Broader aspects of neutrophil function and apoptosis at the expected neutrophil nadir 4 days
33 following TCZ administration have not been assessed, and no studies have been undertaken
34 to examine the effects of IL-6 modulation on *in vivo* whole body neutrophil kinetics in
35 humans. Likewise, to date there is no mechanistic understanding of the decrease in
36 circulating neutrophils following treatment with TCZ. Such data are also required to comply
37 with European Medicines Agency requests on providing further safety information on the use
38 of TCZ. Therefore, an exploratory study was conducted in healthy subjects to investigate the
39 hypothesis that IL-6R blockade affects whole body neutrophil kinetics by affecting neutrophil
40 margination and / or re-uptake by the bone marrow, without affecting neutrophil function and
41 survival.

58 METHODS

59
60

Study subjects

This single-blind, randomized study (ClinicalTrials.gov identifier NCT01991990) enrolled healthy male subjects aged 18-65 years. Subjects had a body mass index between 18 kg/m² and 30 kg/m², were non-smokers, and did not receive any medication other than paracetamol. The study was approved by the East Midlands Nottingham Research Ethics Committee (Reference 13/EM/0350). All subjects provided written informed consent in accordance with the Declaration of Helsinki and local laws and regulations.

Study design

Subjects were randomized to receive a single intravenous dose, blinded to subjects only, of TCZ 8 mg/kg or saline placebo (2:1 randomization) on day 0 (Figure 1A). No subjects experienced clinically significant Common Terminology Criteria (CTC) grade 3 or 4 neutropenia (neutrophil count below $1 \times 10^9/L$). However, there was a wide variation in the relative reduction in blood neutrophil count following TCZ; therefore in the analysis TCZ-treated subjects were divided into two equal-sized groups to examine the effects of IL-6R blockade based on the extent of the decrease in their neutrophil count. This grouping was result-driven and not pre-defined.

Neutrophil isolation

Neutrophils were isolated from peripheral blood using dextran sedimentation and discontinuous plasma-Percoll (Fisher Scientific, Loughborough, UK) gradient centrifugation, as previously described [21].

Neutrophil function and apoptosis *ex vivo*

Neutrophil function and apoptosis were assessed *ex vivo* on day 0 (pre-dose) and day 4 (post-dose). Respiratory burst was measured in neutrophils, primed with tumor necrosis factor- α (TNF α , 20 ng/mL; R&D, UK) or phosphate-buffered saline (PBS) control for 30 minutes, as the peak in N-formyl-methionyl-leucyl-phenylalanine (fMLP; Sigma-Aldrich, UK)-stimulated, horseradish peroxidase (HRP; Sigma-Aldrich, UK)-catalyzed luminol (Sigma-Aldrich, UK) chemiluminescence [22]. Phagocytosis was assessed in neutrophils equilibrated at 4°C or 37°C for 1 hour followed by addition of heat-killed, eFluor670 (eBioscience, UK)-labeled *Streptococcus pneumoniae* (ratio 1 PMN : 29 *S. pneumoniae*) for 1 hour, and quantified by flow cytometry [23].

For assessment of apoptosis, neutrophils were incubated for 20 hours with vehicle control or a pro-survival factor, either GM-CSF (1 ng/mL; R&D, UK) or TNF α (20 ng/mL), and apoptosis was quantified by annexin V-FITC and propidium iodide (PI) (BD Biosciences, UK) staining, with early apoptotic cells being annexin V⁺/PI⁻ and late apoptotic cells annexin V⁺/PI⁺. Cytospin slides were also generated and stained with Diff-Quik staining (Gamidor, UK), and neutrophil morphology examined in a minimum of 300 neutrophils per slide using oil immersion light microscopy with the assessor blinded to treatment conditions. Apoptotic cells were identified by their darkly stained, pyknotic nuclei [24].

Surface markers were measured in fresh (0 min), PBS control (30 min) and fMLP-stimulated (30 min) neutrophils incubated for 30 minutes with the anti-human antibodies CD11b-BV421, CD16-FITC, CD62L-APC and CD162-PE, or isotype controls (BD Biosciences, UK). Expressions were quantified as median fluorescence intensities (MFI) by flow

1
2
3 cytometry. Shape change was assessed by median forward scatter (FSC). Data were analyzed
4
5 using FlowJo software.

10 *Neutrophil kinetics in vivo*

11
12
13 Autologous neutrophils were isolated from peripheral blood by Hetastarch (Grifols, UK)
14
15 sedimentation and discontinuous plasma-Percoll gradient centrifugation. Neutrophils were
16
17 harvested and labeled with indium-111 (^{111}In ; Mallinckrodt, UK) chelated to tropolone
18
19 (Ipswich Pharmacy Manufacturing Unit, UK) by incubation at room temperature for 10
20
21 minutes, subsequently washed twice in platelet-poor plasma and re-injected (maximum 2.5
22
23 MBq) into the subjects [25,26].
24
25
26
27
28
29

30
31 Blood was sampled 45 minutes post re-injection to determine the percentage recovery of
32
33 radiolabeled neutrophils, as previously described [26]. Longitudinal whole body profiles were
34
35 generated in a fully shielded whole body gamma-counter at 45 minutes (day 4), 1 day (day 5)
36
37 and 6 days (day 10) following re-injection. For each scan, the collimated anterior and
38
39 posterior detectors moved from head downwards at 14 cm/min for 10 minutes (Figure 5A).
40
41 Counts were background and decay corrected, and geometric means normalized to day 4
42
43 counts.
44
45
46
47
48

49 *Safety*

50
51
52 Safety was assessed by physical examination, vital signs, and monitoring of adverse events
53
54 and laboratory parameters. All subjects completed all study and safety visits.
55
56
57
58
59
60

Statistical analysis

All *ex vivo* assays were performed in triplicate. Data are presented as mean \pm SEM of (n) independent experiments, and analyzed using GraphPad Prism version 6. Treatment groups were compared using one-way ANOVA and unpaired t-tests with Holm-Sidak correction for multiple comparisons.

RESULTS

Study subjects

A total of 18 subjects were treated with a single intravenous dose of TCZ 8 mg/kg (n = 12) or saline placebo (n = 6) on day 0. There was a significant reduction in day 4 neutrophil count in TCZ-treated ($p < 0.001$) but not placebo-treated subjects (Figure 1B-C). In the TCZ-treated subjects, splitting the groups evenly resulted in 6 subjects with $< 51.3\%$ relative reduction in day 4 neutrophil count (TCZ-PMN-‘high’ group) and 6 subjects with $> 51.3\%$ relative reduction in day 4 neutrophil count (TCZ-PMN-‘low’ group). No subjects experienced CTC grade 3 or 4 neutropenia. Mean neutrophil counts at day 4 as % baseline were 101.9% in the placebo group, 68.3% in the TCZ-PMN-high group, and 44.2% in the TCZ-PMN-low group ($p < 0.001$; Figure 1D).

Neutrophil function and apoptosis ex vivo

Respiratory burst activity was intact at days 0 and 4 in neutrophils isolated from placebo, TCZ-PMN-low, and TCZ-PMN-high groups; mean peak chemiluminescence did not show statistically significant differences between the unprimed groups, or between the TNF α -primed groups (Figure 2A,D-E). Rates of phagocytosis of heat-killed *S. pneumoniae* were

1
2
3 also similar in all groups, indicating intact phagocytic activity (Figure 2B-C,F-G). Neutrophil
4
5 survival following 20 hours of *ex vivo* culture was unaffected by TCZ, with apoptosis rates
6
7 showing no differences between placebo and TCZ groups under either untreated conditions or
8
9 in the presence of the pro-survival factors GM-CSF or TNF α (Figure 3). Cell surface markers
10
11 of neutrophil activation, including CD11b, CD62L, CD162, and shape change [27-29], were
12
13 likewise unaffected by TCZ in both control and fMLP-stimulated neutrophils (Figure 4A-
14
15 B,D-G). Expression of CD16, a marker expressed on mature neutrophils, and declines on
16
17 aging neutrophils [30], was also unaffected by TCZ (Figure 4A,C).

21 22 23 24 *Neutrophil kinetics in vivo*

25
26
27 For analysis of the *in vivo* kinetic data, one subject from the TCZ-PMN-high group was
28
29 excluded because of external (skin) contamination, which affected the profiling data. The
30
31 mean (SEM) 45-minute blood recovery values of ^{111}In -labeled neutrophils at day 4 as % total
32
33 body count were 26.7 (4.7) in the placebo group (n = 6), 28.4 (2.5) in the TCZ-PMN-high
34
35 group (n = 5) and 29.9 (5.9) in the TCZ-PMN-low group (n = 6) (Figure 5B); these were not
36
37 significantly different, indicating a similar extent of early neutrophil intravascular
38
39 margination in all groups. Consistent with these data, in TCZ-treated subjects, there were no
40
41 differences in the distribution of radiolabeled neutrophils in the liver / spleen or pelvic
42
43 marrow pools 45 minutes post re-injection (Figure 5C-D). These data indicate again that the
44
45 kinetics of early neutrophil margination are unaffected following TCZ.
46
47
48
49
50
51
52

53 However, neutrophil re-distribution to, and uptake in, the pelvic marrow region (which could
54
55 be used as an index of generalized bone marrow activity) on days 5 and 10 (1 and 6 days
56
57 following ^{111}In -labeled neutrophil re-injection, respectively) was considerably lower in the
58
59
60

1
2
3 TCZ-PMN-low group (Figure 5E-F); peak pelvic count, as % day 4 count, on day 5 was
4
5 188% in the placebo group, 171% in the TCZ-PMN-high group, and 127% in the TCZ-PMN-
6
7 low group ($p < 0.001$, placebo vs TCZ-PMN-low), whereas on day 10, it was 180% in the
8
9 placebo group, 168% in the TCZ-PMN-high group, and 132% in the TCZ-PMN-low group (p
10
11 < 0.01 , placebo vs TCZ-PMN-low) (Figure 5H). This was associated with a clear trend
12
13 towards higher neutrophil retention in the liver / spleen on days 5 and 10 in the TCZ-PMN-
14
15 low group (Figure 5G), and a correlation between day 10 liver / spleen peak radioactivity and
16
17 day 4 neutrophil count ($r^2 = 0.38$, $p < 0.05$; Figure S1C).
18
19
20
21
22
23

24 *Safety*

25
26
27 There were no adverse events leading to study withdrawal. Overall, 8 subjects experienced 12
28
29 adverse events, and all resolved without sequelae (Table S1). Of the 9 adverse events in the
30
31 TCZ-treated subjects, all were mild or moderate in severity and were consistent with the
32
33 known safety profile of TCZ.
34
35
36
37
38

39 **DISCUSSION**

40
41
42 Anti-IL-6R therapy is an important intervention in inflammatory diseases, and has been used
43
44 successfully in diseases such as rheumatoid arthritis [8,31]. However, concerns have been
45
46 raised about its effects on circulating neutrophil numbers and function. This study is the first
47
48 to assess the pharmacodynamic effects of anti-IL-6R on human neutrophil kinetics *in vivo*
49
50 and the first to comprehensively investigate the effects of IL-6R blockade on neutrophil
51
52 function and apoptosis *ex vivo* at the expected nadir of blood neutrophil count.
53
54
55
56
57
58
59
60

1
2
3 Results of this exploratory study in healthy subjects demonstrated a reduction in neutrophil
4
5 count 4 days after administration of intravenous TCZ, representing the previously defined
6
7 neutrophil nadir following TCZ administration [32]. Neutrophil respiratory burst and
8
9 phagocytic activity remained intact at day 4, suggesting that the capacity of circulating
10
11 neutrophils to respond to pathogens was unaffected at the time point when TCZ has its
12
13 greatest effect on the numbers of circulating neutrophils. These data support the clinical trial
14
15 experience of TCZ use in that no temporal relationship has been demonstrated between
16
17 reductions in neutrophil counts and risks of serious infection [6-10,33].
18
19

20
21
22
23
24 Neutrophils were not activated at baseline after TCZ infusion and responded to *ex vivo* fMLP
25
26 activation to a similar degree to neutrophils from placebo subjects. Rates of apoptosis in *ex*
27
28 *vivo* culture were also unaffected, suggesting that TCZ does not affect the survival of
29
30 circulating neutrophils, whose half-life has been estimated in other *ex vivo* and *in vivo*
31
32 labeling studies ranging from several hours to 3.8 days [34-36]. The systemic administration
33
34 of TCZ makes differential functional effects on neutrophils in the circulating and marginated
35
36 pools unlikely. The current results are consistent with a recent study in healthy subjects and
37
38 patients with rheumatoid arthritis, which showed no effect of TCZ on *ex vivo* neutrophil
39
40 function and rates of apoptosis, when measured 4 and 12 weeks after multiple doses of TCZ
41
42 [13].
43
44
45
46
47
48
49

50 Assessment of whole body kinetics showed that early neutrophil margination was unaffected
51
52 by TCZ, with no difference in neutrophil distribution in the blood, liver / spleen and pelvic
53
54 marrow regions 45 minutes following re-injection of radiolabeled neutrophils. However,
55
56 neutrophil trafficking at later times was significantly different in the TCZ-PMN-low group,
57
58
59
60

1
2
3 as demonstrated by reduced neutrophil re-uptake to the pelvic marrow region, with a trend
4
5 towards higher neutrophil retention in the liver / spleen region on days 5 and 10. These
6
7 findings indicate that TCZ treatment reduces bone marrow re-uptake of neutrophils, either
8
9 directly, or indirectly via a mechanism involving enhanced retention by the liver and spleen.
10
11 The former mechanism would be consistent with the previously defined role of IL-6 in the
12
13 release of neutrophils from the bone marrow compartment in animal models [15,16]. No
14
15 subjects experienced CTC grade 3 or 4 neutropenia. However, the significant relative
16
17 reduction in neutrophil count in TCZ-treated subjects and the differences in neutrophil
18
19 kinetics in the TCZ-PMN-low group demonstrate the biological effects of TCZ even in the
20
21 absence of clinically significant neutropenia.
22
23
24
25
26
27

28
29 The study has several limitations. The control subjects in our study received saline placebo
30
31 rather than irrelevant immunoglobulin G (IgG). Previous studies have shown that IL-6-
32
33 induced STAT-3 phosphorylation is effectively blocked by TCZ but not by IgG in
34
35 neutrophils from healthy subjects [13]; nevertheless, we cannot rule out the possibility of
36
37 non-specific IgG effects on neutrophils in our results.
38
39
40
41
42

43
44 Neutrophil release from the bone marrow was not directly examined in the current model,
45
46 and as such, the effects of TCZ on the release of neutrophils from the bone marrow post-
47
48 mitotic pool in response to a stimulus were not formally assessed. Further investigation is
49
50 required to demonstrate definitively whether IL-6R blockade affects neutrophil de-
51
52 margination and / or release of these cells from the bone marrow.
53
54
55
56
57
58
59
60

1
2
3 The 45-minute blood recovery values of ^{111}In -labeled neutrophils in the current study were
4 slightly lower than previously demonstrated values. This can indicate a degree of cellular
5 damage during the isolation and radiolabeling process. However, there was no evidence of
6 abnormally high margination of radiolabeled neutrophils to the liver / spleen in the placebo or
7 TCZ groups, which would be observed in the case of cellular damage. In addition, it has been
8 demonstrated previously that the current method of neutrophil isolation and radiolabeling
9 does not cause *ex vivo* priming or activation of neutrophils, hence allowing neutrophil
10 kinetics to be studied under physiological conditions [26].
11
12
13
14
15
16
17
18
19
20
21
22
23

24 The whole body profiling data demonstrated the effects of TCZ treatment on neutrophil
25 kinetics *in vivo*, suggesting reduced neutrophil re-uptake to the pelvic bone marrow and some
26 evidence of persistent retention of neutrophils in the liver / spleen either through a failure of
27 de-margination or enhanced neutrophil destruction at these sites. **In humans healthy
28 neutrophils are removed from the circulation in approximately equal proportions in the liver,
29 spleen and bone marrow. This occurs in a seemingly random and age-independent fashion,
30 and does not reflect intravascular apoptosis, which in health is extremely rare. This situation
31 contrasts somewhat to the mouse where aged neutrophils are preferentially removed by the
32 bone marrow and this involves up-regulation of CXCR4 [37]. Following removal from the
33 circulation neutrophils then undergo apoptosis and are efferocytosed by splenic marginal
34 zone and bone marrow stromal macrophages; this later process has been shown to regulate
35 blood neutrophil levels via the production of G-CSF [38,39]. While the role of the IL-6/IL-6R
36 axis in these processes is uncertain, marrow sampling was not part of our study.**

57
58
59
60

1
2
3 Overall, these data suggest that the reduction in circulating neutrophils results in a relative
4 rather than absolute neutropenia in patients treated with TCZ. This observation may help
5 explain why no temporal relationship between CTC grade 3 or 4 neutropenia and serious
6 infection has been observed with TCZ treatment. Further work exploring the release of
7 neutrophils from the bone marrow in the presence of TCZ is warranted.

12
13
14
15
16
17

18 In summary, we have demonstrated for the first time in humans that IL-6R blockade by a
19 single intravenous dose of tocilizumab affects *in vivo* neutrophil trafficking to the bone
20 marrow without influencing the *ex vivo* functional capacity, activation and apoptosis of these
21 cells.

Figure 1. Effect of intravenous TCZ administration on blood neutrophil count. (A)

Study design. (B-C) Day 0 (pre-dose) and day 4 (post-dose) blood neutrophil counts in placebo-treated subjects (n = 6) and TCZ-treated subjects (n = 12). # $p < 0.001$. (D) Day 4 neutrophil count, as % day 0 count, in placebo (n = 6), TCZ-PMN-high (n = 6) and TCZ-PMN-low (n = 6) groups. * $p < 0.05$, # $p < 0.001$ vs placebo; # $p < 0.001$ across three groups. Data shown as mean \pm SEM.

Figure 2. Ex vivo neutrophil respiratory burst and phagocytic capacity following TCZ.

(A) Representative results of respiratory burst measurement by luminol-HRP chemiluminescence. RLU, relative light units. (B) Representative flow cytometry results demonstrating phagocytosis as *S. pneumoniae*-eFluor670 fluorescence. (C) Light microscopy example of a neutrophil containing phagocytosed *S. pneumoniae* (arrow). Original magnification $\times 100$. (D-E) Respiratory burst activity, quantified as (D) absolute and (E) relative peak chemiluminescence, in unprimed (a) and TNF α -primed (b) neutrophils. * $p < 0.05$, † $p < 0.01$, # $p < 0.001$ vs a; ns, non-significant across treatment groups (a and b). (F-G) Phagocytosis of heat-killed eFluor670-labeled *S. pneumoniae*, quantified as (F) MFI and (G) % eFluor670-positive neutrophils, in neutrophil only (a), 4°C (b) and 37°C (c) treatment groups. # $p < 0.001$ vs b; ns, non-significant across treatment groups (c). Placebo, n = 6; TCZ-PMN-high, n = 6; TCZ-PMN-low, n = 6. Data shown as mean \pm SEM.

Figure 3. Ex vivo neutrophil apoptosis following TCZ. (A) Representative flow cytometry

plots of neutrophils following 20 hours of culture showing annexin V and PI staining. (B) Light microscopy example of viable (black arrow) and apoptotic (red arrows) neutrophils. Original magnification $\times 100$. (C-D) Apoptosis following 20 hours of culture, quantified as

1
2
3 (C) % annexin V-positive cells by flow cytometry and (D) % apoptotic cells by microscopic
4 morphology, under untreated (a), GM-CSF-treated (b) and TNF α -treated (c) conditions. * $p <$
5 0.05, † $p <$ 0.01, # $p <$ 0.001 vs a; ns, non-significant across treatment groups (a, b and c).

15 **Figure 4. Ex vivo neutrophil activation following TCZ.** (A) Representative flow cytometry
16 plots of CD11b, CD16, CD62L, CD162 and forward scatter (FSC) in neutrophils stimulated
17 with fMLP *ex vivo*. (B-G) Flow cytometry quantification of surface markers of activation,
18 including (B) CD11b MFI, (C) CD16 MFI, (D) CD62L MFI, (E) CD162 MFI, and shape
19 change, including (F) forward scatter and (G) % shape changed cells, at 0 minute control (a),
20 30 minute control (b) and 30 minute fMLP (c). * $p <$ 0.05, # $p <$ 0.001 vs a; ns, non-
21 significant across treatment groups (a and c). Placebo, n = 6; TCZ-PMN-high, n = 6; TCZ-
22 PMN-low, n = 6. Data shown as mean \pm SEM.
