international science community.

Response to reviewer

We thank the review for thoughtful comments and having edited the text accordingly. The point by point responses are in [blue](#) below.

Reviewer #1: This manuscript reviews the investigations of atmospheric entry probes designed by NASA and ESA. It is suitable for SSRv and I recommend that it should be published after some minor revisions.

1) p2 line 4, 'With the completion of the Galileo...' the authors should mention Juno as a successful mission at Jupiter.

[Noted, and added](#)

2) p4 - p7, Several kinds of numbers (entry angle, entry velocity, heating rate, battery performance, so on) are enumerated as the characteristics of the entry probes. It is difficult for readers to understand how important these numbers are for the entry probes to measure the gas at the planets. It is recommended to add some descriptions to indicate how these numbers would affect finally the scientific results.

[Thank you for this comment – we sometimes forget all readers are not familiar with the details of probe missions and their jargon! We have added a section before the study discussion defining and explaining these parameters, and have revised the Table 1 to better show the comparison of the most critical values.](#)

3) From the title 'Recent mission concepts for...' the readers would expect the overview of the functions of the onboard sensors and the progress of the performance, as well as its relationship with the scientific target of entry probe mission, which are insufficient in the present manuscript. It is recommended to add more descriptions in view of the scientific strategy.

[We purposely kept the description of the science goals and instruments brief for two reasons: 1\) they are described in other papers in this volume in much more detail and 2\) these studies we review have defined the science in detail, but the instruments are only notional and not meant to be the payload that flies. We have addressed this concern by adding a second table that describes the science goals and notional payload from each study in more detail, but we have also changed the title to be more reflective of the paper content: "A review of the *in situ* probe designs from recent Ice Giant mission concept studies" In a few places we have added some words to each concept section.](#)

4) p9 line 13, 'No new technologies are required.' It sounds that the authors are going a bit too far. I suppose that new technologies would get required when new scientific objectives emerge. It would be much better to say that they are able to achieve the proposed scientific targets by the technologies currently available.

[We've changed the wording to:](#)

["The *in situ* scientific goals of these missions can all be achieved with existing instrument technologies, ..."](#)

Abstract

For the Ice Giants, atmospheric entry probes provide critical measurements not attainable via remote observations. Including the 2013-2022 NASA Planetary Decadal Survey, there have been at least five comprehensive atmospheric probe engineering design studies performed in recent years by NASA and ESA. International science definition teams have assessed the science requirements, and each recommended similar measurements and payloads to meet science goals with current instrument technology. The probe system concept has matured and converged on general design parameters that indicate the probe would include a 1-meter class aeroshell and have a mass around 350 to 400-kg. Probe battery sizes vary, depending on the duration of a post-release coast phase, and assumptions about heaters and instrument power needs. The various mission concepts demonstrate the need for advanced power and thermal protection system development. The many completed studies show an Ice Giant mission with an in situ probe is feasible and would be welcomed by the international science community.

Key words: Uranus; Neptune; Mission Concept; Robotic Exploration; Atmospheric Probe

1 **1. Introduction:**

2 Uranus and Neptune remain the only planets in our solar system not to have been visited by a
3 dedicated robotic mission. After the brief Voyager 2 flybys of each in 1986 and 1989,
4 respectively, we were left with sparse scientific data that showed these two planets were vastly
5 different than their gas giant counterparts, Jupiter and Saturn, in composition, internal structure
6 and magnetospheres, satellite and ring systems (Porco et al. 1995, Duncan & Lissauer 1997,
7 Guillot 2005, Masters et al. 2014, Atreya et al. 2018). Perhaps even more fundamentally, solar
8 system formation models have continued to evolve over the past several decades, both to explain
9 the configuration of our own solar system, but also to understand how exoplanet systems may
10 have formed. We do not yet understand the role of the ice giants in planetary migration in our
11 solar system, yet they reside in the same mass range as the majority of the exoplanets (e.g.,
12 Borucki et al. 2011, Turrini et al. 2014).

13

14 For these reasons, and many more, the most recent U.S. Planetary Decadal Survey: Visions and
15 Voyages for Planetary Science in the Decade 2013-2022¹, listed *Uranus Orbiter and Probe* (Ice
16 Giant exploration) as the next in priority after *Mars Astrobiology Explorer-Cacher* (first of three
17 elements of a Mars Sample Return campaign a.k.a. Mars 2020) and *Jupiter Europa Orbiter* (a.k.a.
18 Europa Clipper) both of which are now in development. Indeed, ongoing ground and space-based
19 observations of Uranus and Neptune show that these are active planets, with clouds and storms
20 that form and dissipate on a multitude of time scales that will help reveal more about their deep
21 circulation and energy balance (Sromovsky et al. 2012, Zhang et al. 2015, Kaspi et al. 2016, Irwin
22 et al. 2017, Hsu et al. 2019), Figure 1. However, there are several key measurements that tie to
23 their internal structure and to atmospheric circulation, as well as to their formation, that cannot
24 be inferred from Earth-based observations alone and therefore require remote sensing from a
25 planetary orbiter and *in situ* atmospheric measurements from a probe.

26

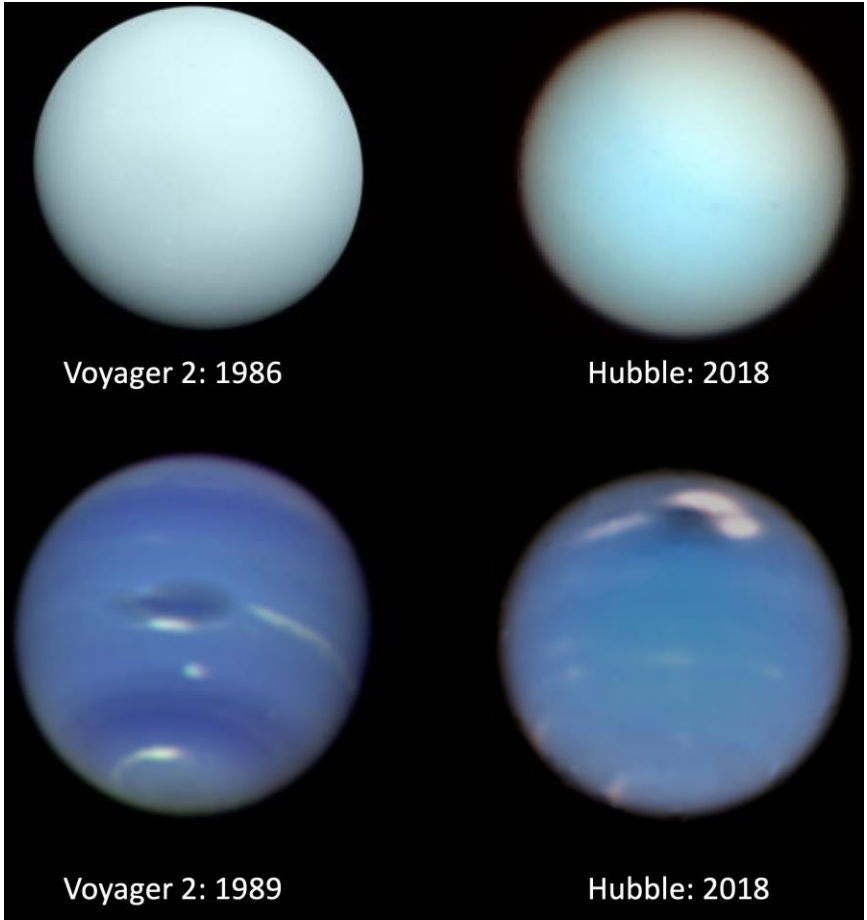

27 The formation and evolution of the giant planets hold many keys to understanding the formation
28 and evolution of the solar system as a whole, including the terrestrial planets, as well as
29 exoplanetary systems (Mousis et al. 2018, Mandt et al., this issue). Atmospheric probes provide
30 the means to make essential atmospheric measurements that indicate when and where a planet
31 formed yet are beyond the reach of remote sensing. These include the abundances of the noble
32 gases including helium, key isotopic ratios such as D/H, ³He/⁴He, ¹⁴N/¹⁵N, ¹²C/¹³C, ¹⁶O/¹⁸O, and
33 abundances and isotopes of other heavy elements (Atreya et al. 2018, and Atreya et al. Wurz et
34 al., this issue). Measurement of disequilibrium species such as PH₃, CO, AsH₃, GeH₄, and SiH₄
35 trace atmospheric upwelling to provide further insight into atmospheric composition and
36 chemistries at much deeper levels and help constrain the bulk oxygen, nitrogen, and sulfur
37 abundances that are not well-mixed at higher altitudes (*c.f.*, Cavalié et al., Fletcher et al., Hueso
38 et al., Mousis et al., this issue). *In situ* atmospheric composition measurements typically require
39 a mass spectrometer and helium abundance detector.

40

41 Other essential measurements only achievable *in situ* include atmospheric thermal structure, and
42 dynamics (winds and waves) below the visible clouds. It is also necessary to directly measure the

¹ <https://www.nap.edu/catalog/13117/vision-and-voyages-for-planetary-science-in-the-decade-2013-2022>

1 location, density, composition, and structure of clouds, and the size distribution of liquid and
2 solid cloud aerosols at altitudes beneath those significantly influenced by sunlight and easily
3 accessible to remote sensing. Measurements of atmospheric thermal structure, dynamics, and
4 physical processes can be obtained by an Atmospheric Structure Instrument, nephelometer, and
5 net flux radiometer. Additional information can be acquired by accelerometers from which the
6 upper atmospheric density profile can be retrieved, and an ultrastable oscillator as part of the
7 telecommunications system to provide wind measurements using Doppler techniques (for more
8 information see Aplin et al., Atkinson et al., Aslam et al., Ferri et al., Renard et al. this issue).
9
10

11
12 Figure 1. Views of Uranus (top) and Neptune (bottom) from spacecraft observations. Hubble
13 Space Telescope observations (right) reveal changes in Uranus’s polar hazes, as well as new dark
14 vortices on Neptune, since the Voyager 2 flybys (left). These features hint at the atmospheric
15 structure that only an *in situ* probe can confirm.
16

17 This paper provides a broad overview of the studies of robotic missions with atmospheric probes
18 that have been completed in the past decade. In Section 2 we briefly summarize the most
19 recently completed NASA and ESA Ice Giant probe studies. Section 3 compares and contrasts the
20 resources needed for an Ice Giant atmospheric probe, and shows the evolution of the designs,

1 and their commonalities, as the science requirements and design have matured. Finally, we
2 summarize with a discussion of the path forward.

3 4 **2. Overview of Mission Concepts:**

5 6 **2.1 NASA Studies**

7 Over the past decade or more, there have been many studies of Ice Giant missions, varying in
8 size, scope and complexity, including those that could fall in NASA's competed program of small-
9 class Discovery and medium-class New Frontiers missions, as well as large-class NASA-directed,
10 strategic Flagship-class missions. With the completion of the Galileo and Juno missions at Jupiter
11 and Cassini at Saturn, the Ice Giants remain as the only planets in our solar system that have not
12 yet been extensively explored with a major NASA, or any other international, mission, a fact that
13 was recognized in the V&V Decadal Survey prioritization mentioned above.

14
15 NASA has completed two large studies of Ice Giant missions with atmospheric probes: the 2010
16 Decadal Uranus Orbiter and Probe Study² and the 2017 NASA/JPL Ice Giant³ study. The former
17 study was a rapid design report of the concept recommended by the Decadal Survey's Giant
18 Planets panel, to determine the cost and technology development needed for either a Uranus or
19 Neptune Flagship mission. Due to the short timescales of the Decadal process, this concept study
20 sought to include a full end-to-end design, but at a low fidelity primarily for costing purposes,
21 and with the understanding that an eventual mission would require studying each aspect of the
22 mission design in more detail. This study was completed using the Johns Hopkins University
23 Applied Physics Laboratory concurrent engineering design lab.

24
25 At the beginning of the Decadal Study, both Uranus and Neptune were considered. The initial
26 Neptune trade space was reliant on a Jupiter gravity assist, which highly constrained the launch
27 window. It was determined that it was not feasible to reach Neptune in a reasonable time scale
28 without the use of aerocapture, which at the time was perceived to be too risky. The final design
29 work thus focused on a Uranus orbiter with probe that included Solar Electric Propulsion (SEP),
30 an Earth gravity assist, and a 13-yr cruise duration; ballistic trajectories to Uranus with Jupiter
31 gravity assists were not possible within the Decadal 2013 to 2022 timescale. Independent
32 costing, which included generous reserves and cost threats from risks, found a full mission cost
33 in the \$2.7 to \$3.3B range, depending on whether SEP was included or not. During the Decadal
34 deliberations a Saturn gravity assist was also analyzed, to demonstrate that multiple options did
35 exist to launch a mission to the Ice Giants, with or without a SEP system.

36
37 The 2017 NASA study was a longer and more detailed study of a variety of possible architectures,
38 to Uranus or Neptune or both, and included flybys, orbiters, and probes in a multitude of
39 configurations. The science definition team examined community recommendations for science
40 requirements, as well as the latest research to determine the priority of the science
41 investigations. A range of remote sensing science instrument options was also evaluated and

² https://sites.nationalacademies.org/cs/groups/ssbsite/documents/webpage/ssb_059323.pdf

³ https://www.lpi.usra.edu/icegiants/mission_study/Full-Report.pdf

1 weighed against the added value of an *in situ* probe (Hofstadter et al. 2019). A major conclusion
2 of the study was that an *in situ* probe is necessary in order to achieve the high science value
3 atmospheric measurements, with priority placed on the elemental and isotopic abundances and
4 atmospheric pressure, temperature, and density measurements.

5
6 For the mission design, relaxing the Decadal survey launch window constraints to the 2030s
7 significantly opened the trajectory trade space, but flight times were limited to <12 years to allow
8 for at least 2 years of science and completion of the mission within the Multi-Mission
9 Radioisotope Thermal Generator (MMRTG) design lifetime constraint. Trajectories that allow a
10 spacecraft to launch to Uranus without a SEP stage were verified to be possible on conventional
11 launch vehicles, particularly when taking advantage of a Jupiter gravity assist. Reaching Neptune
12 within the required time, however, still required a SEP stage. Next generation launch vehicles
13 would also allow for shorter flight times and/or bigger payloads to both planets. The engineering
14 design work was then completed in a modular fashion, to allow the rapid comparison of many
15 architectural options to determine the sweet spot balance between cost and science return. For
16 comparison purposes, lowest cost missions included a single planet flyby with or without a probe,
17 and the higher end included a fully instrumented orbiter and atmospheric probe to one or both
18 planets. Thus, a suite of potential mission architectures, with different payloads and concepts of
19 operations were studied, with a common probe design for both Neptune and Uranus. In terms
20 of science per dollar, the optimal strategic (Flagship) mission is an orbiter with an atmospheric
21 probe. Final costs for this mission are ~\$2 to \$2.2B, depending on which planet is visited, and
22 whether a SEP system is needed.

23 24 **2.2 ESA Studies:**

25 European scientists regularly propose missions to study the Solar System via mission opportunity
26 calls issued by the Science Programme of the European Space Agency (ESA), whose strategic
27 program of space science missions currently in operation or development is known as the Cosmic
28 Vision 2015-2025⁴ while the next long-term planning for ESA science space missions is called
29 Voyage 2050⁵. The program, which consists of large (L), medium (M), small (S) and fast (F) class
30 missions, is a successor to the previous Horizon 2000+ program, which provided both the Rosetta
31 mission to Comet 67P and the BepiColombo mission to Mercury. At the time of writing, ESA's
32 Cosmic Vision planetary science missions include the L-class Jupiter Icy Moons Explorer (JUICE,
33 Grasset et al. 2013), scheduled to launch in 2022, and the F-class Comet Interceptor mission,
34 scheduled for launch in 2028. In addition, ESA's Human and Robotic Exploration program
35 includes ESA's ExoMars Trace Gas Orbiter (TGO, 2016) and the launch of the ExoMars Rosalind
36 Franklin rover in 2020. Several mission concept proposals have been submitted for the
37 exploration of the Ice Giants at each opportunity and received strong signs of broad recognition
38 of the importance of the objectives, but at this time there are no accepted concepts for European
39 exploration of these planets. Nevertheless, the past decade has seen a flurry of activity in mission
40 concept development, including both orbital missions and *in situ* entry probes for the giant
41 planets.

⁴ <http://sci.esa.int/cosmic-vision/38542-esa-br-247-cosmic-vision-space-science-for-europe-2015-2025/>

⁵ <https://www.cosmos.esa.int/web/voyage-2050>

1 A Uranus orbiter, based heavily on heritage from Mars Express and Rosetta, was submitted to
2 both the M3 (2010) and M4 (2015) calls for medium-class mission proposals (Arridge et al. 2012).
3 However, this proposal was not selected for a Phase A study. Nevertheless, the European
4 community had another opportunity to showcase the potential of Ice Giant science with multiple
5 submissions to ESA's call for large-class mission themes in 2013: a Uranus orbiter with
6 atmospheric probe (Arridge et al. 2014), an orbiter to explore Neptune and Triton (Masters et al.
7 2014); and a concept for dual orbiters of both worlds (Turrini et al. 2014). Once again, an Ice
8 Giant mission failed to proceed to the formal study phase. ESA's Senior Survey Committee (SSC⁶)
9 however recognized the theme as a high-priority one and recommended that every effort be
10 made to pursue this science theme through other means, such as cooperation on missions led by
11 partner agencies. With inputs to Voyage 2050⁵, the European community has demonstrated the
12 importance of Ice Giant exploration as a cornerstone of ESA's future science program (Fletcher
13 et al. 2019).

14
15 Each of these mission concepts proposed by European scientists recognized the importance of
16 flying an atmospheric entry probe, to address questions about planetary origins and
17 atmospheres. Alongside the Ice Giant proposals, European scientists are developing the science
18 case for *in situ* exploration of Saturn's atmosphere as a logical successor to Cassini's orbital
19 exploration of Saturn (Mousis et al. 2014). The Hera Saturn probe mission was proposed to ESA's
20 M4 and M5 competitions (Mousis et al. 2016) but recognized that an international partnership
21 would be needed to provide the carrier spacecraft to Saturn, and the thermal protection system
22 and aeroshell.

23 24 **3. Probe Design and Resources**

25
26 The following sections will discuss the probe designs that resulted from the individual science
27 and engineering studies. For each of the studies, the designs were guided by the science goals,
28 but also constrained by the basic physics of atmospheric entry. First, the overall mass of an
29 atmospheric probe is driven by the science payload, avionics, batteries, heat shield, and so on.
30 The use of radioisotope heater units (RHUs) can be used to reduce or eliminate battery-powered
31 heaters but were not assumed in all cases. The volume and power needs of the science payload
32 also drive battery sizing, as well as the dimensions of the probe itself. As the probe grows, the
33 amount of heating it encounters will also increase, which then requires more heat shield
34 material, further increasing the mass. Thus, each design is a fine balance of the science needs
35 and mass, power, and volume limitations.

36
37 For each probe design, we will first briefly describe the overall science goals and pressure range
38 to be sampled. Then we will describe a number of the final design assumptions, including coast
39 time from probe separation to entry and descent time, as these can affect battery size and
40 communication and avionics needs. For engineering parameters, we also list the probe trajectory
41 entry angle and velocity. Entry angle and velocity, as well as probe dimensions and shape,

⁶ <http://sci.esa.int/cosmic-vision/53261-report-on-science-themes-for-the-l2-and-l3-missions/>

1 constrain the heat and deceleration forces that the probe experiences⁷. The entry angle is
 2 defined as the angle between the velocity vector of the probe and the horizontal plane of the
 3 local atmosphere; by definition it is always negative (D’Amario et al. 1992). The resultant heat
 4 load determines the heat shield thickness required, while the instruments and avionics must be
 5 capable of withstanding the deceleration forces, usually given in terms of gravity load. Lastly, we
 6 include the battery sizes assumed based on the power needs of the instruments and avionics,
 7 and their operational times. Small changes in any of these parameters ripple through the entire
 8 probe design, thus it is valuable to know what set of values produces a design that is feasible.
 9 The comparative summary of the overall probe characteristics is shown in Table 1.

10
 11

Table 1. Summary of probe design characteristics

| Study | Probe Depth (bars) | Descent Time (mins) | Entry Angle | Total Mass (kg) | Diam. (m) | Entry Velocity (km/s) | Peak Deceleration (g) |
|----------------------------------|--------------------|---------------------|---------------------------------|-----------------|-----------|-----------------------|-----------------------|
| 2010 Decadal Uranus Probe | 5 | 60 | -68° (Uranus) | 127 | 0.76 | 22.4 | 390 |
| 2010 ESA Ice Giant Probe | 100 | 120 90 | -45° (Uranus) -35° (Neptune) | 313 | 1.25 | 21.7 24.7 | 300 325 |
| 2017 JPL Saturn Probe | 10 | 90 | -14° (Saturn) | 296 | 1.25 | 26.9 | 37 |
| 2017 NASA Ice Giant Probe | 10 | 60 | -30° (Uranus) -16° (Neptune) | 321 | 1.20 | 22.5 22.6 | 165 125 |
| 2018 ESA Ice Giant Probe | 10 | 90 | -35° (Neptune) | 342 | 1.35 | 23.1 | 118 |
| 2019 ESA Ice Giant Probe | 10 | 75* | -25° to -45° (Uranus) | 420 | 1.35 | < 26 | Not provided |

12 * The science requirement was a 90-min descent, but probe-carrier relay communication was only
 13 possible for ~75 minutes.

14

15 3.1 NASA 2010 Ice Giant Probe

16 The Decadal probe design study was somewhat limited in scope due to the compressed timeline
 17 needed to meet the Decadal study schedule and to obtain an independent cost and risk
 18 assessment before deliberations. As mentioned above, only the Uranus mission design was
 19 completed for review. The initial design was based on the Pioneer Venus Probe, and assumed
 20 science operations from 0.1 to 5 bars, with primary science goals of determining noble gas
 21 abundances and isotopic ratios of H, C, N, and O, and temperature and pressure profiles.
 22 Instrument heritage was based on the Galileo Probe mass spectrometer (MS), atmospheric
 23 structure (ASI) and Pioneer Venus nephelometer instruments. A New Horizons-like Ultrastable

⁷ <https://ntrs.nasa.gov/archive/nasa/casi.ntrs.nasa.gov/20130014035.pdf>

1 Oscillator (USO) was also included. A more complete summary of notional instrument
2 characteristics and science goals is shown in Table 2.

3
4 The mission concept of operations assumed a 29-day coast after release, with avionics and
5 communication links initiated by timers. The thermal protection system (TPS) was assumed to
6 be provided by a heritage carbon phenolic front and back shield. With an 0.76-m diameter
7 aeroshell, this probe is the smallest of all the designs we discuss, in part because of the limited
8 payload, Table 1. The probe instrument and avionics were powered with a Lithium-ion battery
9 (1.4 kW-hr capacity) and assumed 4 RHUs to maintain minimum temperatures during the coast
10 phase.

11
12 Beyond the availability of the heritage TPS, a large remaining risk in this design concerned the
13 timing of probe entry compared with Uranus orbit insertion. Owing to the lack of knowledge
14 about the region between Uranus and the rings, the orbit insertion maneuver occurs at a safe
15 distance of 1.3 R_U , and to maintain communications the probe entry was constrained to begin 2
16 hours prior to orbit insertion. The entry angle was assumed to be -68° , with an entry velocity of
17 22.35 km/s. The chosen entry path resulted in a peak deceleration of ~ 390 g and a peak heating
18 rate of 5511 W/cm² (total heat load of 38.1 kJ/cm²).

19

20
21 Figure 2. Probe designs from the 2010 Decadal study (left), 2017 NASA study (middle) and the
22 2018 ESA study (right). All employed a spherical pressurized descent vessel and $\sim 45^\circ$ blunt-nose
23 front shield. However, the diameter and mass of the aeroshell have increased significantly since
24 the 2010 study.

25

26 3.2 JPL 2017 Saturn Probe

27 Since the Decadal Survey, many Discovery and New Frontiers with atmospheric probes have been
28 proposed. Although not Ice Giant specific, these proposals allowed for in-depth study of probe
29 designs, and those lessons have been applied to Ice Giant probes, as appropriate. One such
30 mission was the 2017 Saturn Probe proposed for the 4th New Frontiers opportunity in 2018.
31 Much like an Ice Giant probe, key measurements included the bulk abundance and isotope ratios
32 of the noble gases and C, N, O, and S, as well as directly sampling the vertical profiles of
33 temperature, pressure, cloud layers and atmospheric dynamics (Banfield et al. 2018). With an
34 emphasis on high mass resolution for isotopic measurements, this probe included a more
35 advanced mass spectrometer with tunable laser spectrometer, Table 2.

1
2 This concept assumed an aeroshell diameter of 1.25-m with Heat-shield for Extreme Entry
3 Environment Technology (HEEET) TPS on the front heatshield and SLA-561V (a Lockheed heritage
4 honeycomb material) TPS on the backshell⁷. The Saturn entry environment is more benign than
5 that of the Ice Giants; with a -14° entry angle the peak deceleration is 37 g with a peak heating
6 rate of 2362 W/cm². One unique aspect of this design is that it did not include the use of RHUs
7 and relied entirely on battery-powered heaters as a cost-saving measure. With a 30-day coast
8 period, this resulted in a much larger battery system than the other probes described here (6 kW-
9 hr capacity).

10
11
12

Table 2. Summary of study science payload and objectives

| Study | Notional Payload | Data Volume (Mb) | Total Instrument Mass (kg) | Total Avg. Instrument Power (W) | Science Objectives |
|---|---|------------------|----------------------------|---------------------------------|--|
| 2010 Decadal Uranus Probe | MS ASI USO Nephelometer | ~4 | 17.1 | 21.7 | Bulk composition, cloud properties, tropospheric 3-D flow |

13 * The camera and photometer are remnants of the initial Venus design. The science definition team
14 recommended including a He abundance detector, net flux radiometer, and nephelometer.

15

16 3.3 NASA 2017 Ice Giant Probe

17 In the follow-on Ice Giant study, JPL revisited the probe design and concept of operations to
18 assess the payload suite, TPS material, delivery assumptions, and entry details. The Science Team

1 found that much of the probe science priorities remained the same, with a need for an ASI, MS,
2 and nephelometer. However, the payload was expanded to include an H₂ ortho/para sensor, as
3 this was deemed a critical Ice Giant measurement. While the heritage for most instruments
4 remained the same, the Cassini-Huygens probe gas chromatograph mass spectrometer (GCMS)
5 was assumed; the 2010 study underestimated the mass of the Galileo MS, but both are smaller
6 than the Huygens GCMS. This resulted in a larger probe instrument payload mass and power
7 (Table 2) but higher capability. The power levels are not significantly different from the 2010
8 design, and probe power is provided by a Li-ion battery (1 kW-hr capacity).

9
10 For the probe design, it was desired to have a probe that worked at either Uranus or Neptune,
11 and subsystems were sized for the worst-case Uranus communication link and the worst-case
12 Neptune entry heating. The probe delivery also assumed a longer 60-day coast after separation
13 and a much closer flyby with a 1.05 R_U orbit insertion. This design requires 19 RHUs for
14 instrument and avionics heating during the long coast. In the 2010 study the high g loads that
15 would have been difficult for the instruments to accommodate. The entry angle was set to -30°
16 to limit deceleration g-loads on the payload and meet thermal and telecommunication
17 constraints, resulting in a maximum 165 g load and heat load of 41.1 kJ/cm².

18
19 While the 2010 Decadal study assumed heritage carbon phenolic and a scaled aeroshell from
20 Pioneer Venus, the 2017 probe design assumed HEEET TPS material on the front heatshield and
21 phenolic impregnated carbon ablator (C-PICA) on the backshell. Coupled with the larger heat
22 loads and probe size, a more detailed analysis found a much larger aeroshell mass over the 2010
23 probe design, as detailed in the 2017 study report³. This accounts for the majority of the
24 difference in the probe masses in Table 1.

25 26 **3.4 ESA Probe Designs**

27 Following the joint NASA-ESA science definition work in 2016-17, the agencies agreed to consider
28 a palette of possible mission contributions from the European Space Agency to a NASA-led
29 mission, keeping in mind the need for clean interfaces for the stand-alone element. The ESA
30 study⁸, carried out in October-December 2018, focused on potential opportunities to launch in
31 the 2029-2034 window, using Jupiter for a gravity assist. The study looked at three different
32 potential contributions – a second orbiter complementary to a NASA spacecraft; a lander for
33 Triton, and an atmospheric probe to either Uranus or Neptune. The aim was to develop
34 conceptual designs, understand mission-enabling technology needs and the
35 programmatic/scheduling/cost constraints.

36
37 The atmospheric probe study followed a 2010 ESA study on planetary entry probes⁹ and required
38 a payload operating between 1 and 10 bars for a 90-minute descent under parachute, Table 1.
39 This shallow probe could provide insights into both the origins of the Ice Giants (via
40 measurements of atmospheric composition, particularly the noble gases) and the processes
41 shaping planetary atmospheres. The probe consisted of a spherical pressurized vessel containing

⁸ <http://sci.esa.int/future-missions-department/61307-cdf-study-report-ice-giants/>

⁹ <http://sci.esa.int/sci-fmp/47568-pep-assessment-study-internal-final-presentation/>

1 the payload, and the front and back shields were comprised of carbon phenolic TPS material. The
2 combined probe mass was 342 kg with TPS and payload, and notionally contained the same
3 payload as the 2010 ESA study. The science instrumentation was based on a Venus atmospheric
4 payload. However, it was recognized that newer, and more specific, instrument technology, e.g.,
5 GCMS with tunable laser spectrometer and/or Helium abundance detectors, would be desirable
6 and could likely be accommodated in the future; the probe entry site would also be visible from
7 Earth for secondary tracking.

8
9 Four Li-ion batteries would provide the probe power (1.35 kW-hr), with heating from 31 RHUs
10 allowing the probe to survive a 20-day coasting phase after separating from the orbiter.
11 Compared with the 2010 ESA study, the mass of the TPS was larger, and the desired length of
12 time at low pressures was lengthened (reducing the pressure vessel size but increasing the
13 required size of the main parachute). In contrast, the Galileo probe to Jupiter had a more rapid
14 descent, and therefore a smaller parachute. Furthermore, the probe architecture studied by ESA
15 had a data rate twice as high as Galileo, thus a larger battery was needed for transmission. The
16 2018 study focused on Neptune (with only small deltas required for Uranus), but it was noted
17 that the assumed equatorial entry site, with a prograde velocity orientation, was not consistent
18 with a Neptune tour that might be optimized to study Triton (which is on a retrograde orbit
19 around Neptune).

20
21 Following the 2018 report, a delta study was completed in March-May 2019, with the objective
22 to further iterate on the design of the orbiter and of the atmospheric probe. In particular, the
23 mission analysis for a Uranus mission was revisited as a stand-alone ESA mission, as well as
24 making a probe that was suitable to either Uranus or Saturn. RHUs were also removed, and the
25 coast time shortened to 5 days to reduce battery needs. Allowing for a common design increased
26 the probe mass to 420 kg with margin to accommodate thicker heat shields. Although no changes
27 in the payload were investigated beyond that of the 2010 study, the extra mass allows for the
28 additional Ice Giant-specific instrumentation (e.g., Helium abundance detectors, nephelometer,
29 net-flux radiometer) recommended in the 2018 and May 2019 reports and will be investigated in
30 the future.¹⁰

31 32 **4. Discussion**

33 Despite their independent approach, the NASA and ESA mission concepts and probe designs have
34 several similarities, notably in the general configuration, size, and shape of the *in situ* probe (Fig.
35 2), which is expected as the science objectives agree in their priorities. However, the earliest
36 studies significantly underestimated the aeroshell size and mass due to assumptions about TPS
37 materials and their properties. Additionally, most of the early trajectory designs had very large
38 peak decelerations, beyond what instruments can typically handle. As the fidelity of the designs
39 has matured, battery sizes and numbers of RHUs have also increased.

40
41 The 2017-2018 ESA and NASA studies converged on probe mass, although with differences in the
42 numbers of RHUs and payload mass. It would be fair to assume that any mission will need to

¹⁰ <https://sci.esa.int/web/future-missions-department/-/61471-epig-cdf-study-summary-report>

1 accommodate an *in situ* probe with approximately a 1 kW-hr Li-ion battery, 20-30 RHUs for
2 thermal control during the coast phase, and a mass in the 350 to 400-kg range. These parameters
3 depend on the assumed probe coast time, and entry conditions, including entry angle and
4 telecommunications duration, but given the different coast times and entry assumptions
5 between the 2017 NASA and 2018 ESA studies, it is heartening that both reached similar design
6 conclusions. Certainly, the long probe coast time and short window between entry and orbit
7 insertion are lingering concerns from these studies, so the 2019 ESA study with a short coast time
8 is encouraging. Other areas recommended for further work from the 2017 NASA study included
9 completing the development of enhanced MMRTGs (eMMRTGs) and HEEET and further ground-
10 based research of the near-planet ring environment to better optimize orbit insertion timing and
11 distance.

12
13 The 2017 NASA study team also recognized the value of international collaboration and
14 contributions, even though such contributions were not specifically included in the design and
15 mission costing. Contributed instruments or the full *in situ* probe could be most easily
16 incorporated to a NASA-led mission because of the clean interfaces, as compared with the
17 provision of a main spacecraft subsystem. Indeed, the 2018 ESA study concluded that the probe
18 architecture was viable as a contribution to a NASA-led mission. The 2018 report primarily
19 stressed the need for (i) further understanding of heat loads and the characteristics of the
20 thermal protection system, trading off between carbon-phenolic ablators or carbon-carbon
21 ceramic material; (ii) international facility to provide representative test conditions for TPS
22 materials.

23
24 A last consideration is the time criticality for initiating an Ice Giant mission. For Ice Giant system
25 science there is the desire to potentially visit at times when the satellite hemispheres not
26 observed by Voyager 2 may be viewable or, for Triton, when the south pole is still illuminated.
27 From a science perspective, there is no real time constraint on when an atmospheric probe
28 should enter. One consideration however, is accommodating the entry probe. A Jupiter gravity
29 assist allows more mass to be delivered to the Ice Giant systems, including an entry probe, on
30 currently available commercial launch vehicles. In addition, many spacecraft components have
31 reliability ratings up to 18 years, and end of life power for radioisotope power systems becomes
32 problematic for long missions; current MMRTGs have a 14-year design life¹¹. To take advantage
33 of a Jupiter gravity assist the ideal launch windows are in the late 2020s through early 2030s,
34 with opportunities for Neptune around 2030, Uranus in 2034, and dual-spacecraft dual-planet in
35 2031.

36 37 **5. Summary and Next Steps**

38 Although neither an Ice Giant orbiter nor an *in situ* atmospheric probe have been initiated as part
39 of either ESA's or NASA's current mission portfolios, the considerable engineering work
40 completed over the past decade has verified feasibility and significantly matured the mission

¹¹ https://rps.nasa.gov/resources/58/multi-mission-radioisotope-thermoelectric-generator-mmrtg/?category=fact_sheets

1 concept designs. These ongoing studies have opened the door to strong international
2 collaborations and have advanced the possibility that an Ice Giant exploration mission could be
3 achieved in the decade of the 2030s. The Cassini-Huygens mission, with ESA-provided scientific
4 instrument and Titan entry probe, is an example of a highly successful joint international mission
5 of this magnitude. Studies completed by both NASA and ESA show this is an optimal time for an
6 Ice Giant launch using existing launch vehicle capabilities. The *in situ* scientific goals of these
7 missions can all be achieved with existing instrument technologies, but completion of planned
8 advanced radioisotope power systems and entry probe thermal protection systems are critical to
9 a successful mission.
