Search for Higgs Boson and Observation of Z Boson through Their Decay into a Charm Quark-Antiquark Pair in Boosted Topologies in Proton-Proton Collisions at $\sqrt{s} = 13$ TeV

A. Tumasyan *et al.*[*]
(CMS Collaboration)

(Received 25 November 2022; revised 9 April 2023; accepted 11 April 2023; published 26 July 2023)

A search for the standard model (SM) Higgs boson (H) produced with transverse momentum (p_T) greater than 450 GeV and decaying to a charm quark-antiquark ($c\bar{c}$) pair is presented. The search is performed using proton-proton collision data collected at $\sqrt{s} = 13$ TeV by the CMS experiment at the LHC, corresponding to an integrated luminosity of 138 fb^{-1}. Boosted $H \to c\bar{c}$ decay products are reconstructed as a single large-radius jet and identified using a deep neural network charm tagging technique. The method is validated by measuring the $Z \to c\bar{c}$ decay process, which is observed in association with jets at high p_T for the first time with a signal strength of $1.00^{+0.17}_{-0.14}(\text{syst}) \pm 0.08(\text{theo}) \pm 0.06(\text{stat})$, defined as the ratio of the observed process rate to the SM expectation. The observed (expected) upper limit on $\sigma(H)\mathcal{B}(H \to c\bar{c})$ is set at 47 (39) times the SM prediction at 95% confidence level.

DOI: 10.1103/PhysRevLett.131.041801

The standard model (SM) Higgs boson (H) has been observed at the LHC [1–3] in all its expected primary production modes and most of its dominant decay channels. With the observations of direct couplings to τ leptons [4,5], top quarks [6,7], and bottom quarks [8,9] confirming that the SM Yukawa sector gives rise to the masses of third-generation fermions, attention naturally turns to probing the second generation, specifically muons and charm quarks.

The search for H decays to muon pairs is the most experimentally accessible channel, and has been explored by the ATLAS [10,11] and CMS [12] Collaborations. The latter recently found evidence of the H coupling to muons [13].

In contrast, the search for H decays to charm quark-antiquark pairs ($H \to c\bar{c}$) is considerably more challenging, because of the difficulty of identifying such decays and due to the enormous multijet background. However, recent advances in jet substructure and flavor tagging techniques [14] have greatly improved the experimental sensitivity to this decay mode. Prior searches by ATLAS [15,16] and CMS [17,18] have focused on H production in association with a vector boson (VH, where V stands for a W or Z boson), which benefits from strong background rejection thanks to leptonic decays of the vector bosons. The gluon-gluon fusion (ggF) and vector boson fusion (VBF) production modes have larger cross sections, but have yet to be explored.

This letter reports on the first search for the $H \to c\bar{c}$ decay at the LHC, where the H is produced with transverse momentum (p_T) greater than 450 GeV, enriched in events from the ggF production. The search employs the same general strategy as earlier CMS searches for boosted H in the $b\bar{b}$ decay channel [19,20], but uses new mass decorrelated discriminators to define a charm-enriched signal region. This search strategy provides an additional constraint on the decay process to the existing ATLAS and CMS measurements, in terms of production mode and H p_T.

The search is performed using a dataset of proton-proton collisions at $\sqrt{s} = 13$ TeV, collected with the CMS detector at the LHC, and corresponding to an integrated luminosity of 138 fb^{-1}. Candidate events are selected by requiring a high-p_T, large-radius jet with substructure observables compatible with those expected from an $H \to c\bar{c}$ decay. Deep neural network (DNN) discriminators are employed to separate the H signal events from the dominant background, specifically quantum chromodynamics (QCD)-induced multijet events. The discriminators are designed to be independent of jet mass, which allows for both an estimation of the QCD background from control samples in data and for the validation of the analysis procedure through a search for $Z \to c\bar{c}$ decays. A model of the jet mass distributions for the $H \to c\bar{c}$ and $Z \to c\bar{c}$ signals, QCD multijet events, and other background processes is fit simultaneously in several disjoint signal and control regions to extract the signal production cross sections.

The CMS apparatus [21] is a multipurpose, nearly hermetic detector, designed to trigger on [22,23] and identify electrons, muons, photons, and (charged and neutral) hadrons [24–26]. A global "particle-flow" (PF) algorithm [27] aims to reconstruct all individual particles in an event, combining information provided by the all-silicon inner tracker and by the crystal electromagnetic and brass-scintillator hadron calorimeters, operating inside a 3.8 T superconducting solenoid, with data from the gas-ionization muon detectors embedded in the flux-return yoke outside the solenoid. The reconstructed particles are used to build τ leptons, jets, and missing transverse momentum (p_T^{miss}) [28–30].

Simulated samples of signal and background events are produced at the matrix element level using various Monte Carlo (MC) event generators. The QCD multijet, $Z+$jets, and $W+$jets processes are modeled at QCD leading order (LO) accuracy using the MADGRAPH5_aMC@NLO v2.4.2 generator [31]. The vector boson samples contain decays to all flavors of quarks, and include up to 3 (4) extra partons at the matrix element level for $V+$jets events. Jets from the matrix element calculations and the parton shower description are matched using the MLM prescription [32]. The $t\bar{t}$ and single top quark processes are modeled at next-to-LO (NLO) using POWHEG 2.0 [33–38]. The diboson processes are modeled at LO accuracy with PYTHIA8.226 [39]. For 2016 data-taking conditions, QCD samples are modeled with MADGRAPH5_aMC@NLO v2.2.2, and diboson samples are modeled with PYTHIA8.205.

The differential cross sections for the $Z+$jets and $W+$jets ($V+$jets) samples are corrected with boson p_T-dependent functions for higher-order QCD and electroweak (EW) effects. The QCD NLO corrections are derived using MADGRAPH5_aMC@NLO, simulating W and Z production with up to two additional partons and the FxFx matching to the parton shower [40]. The EW NLO corrections are taken from theoretical calculations of Refs. [41–44]. Additionally, the total cross sections for the diboson samples are corrected to next-to-NLO (NNLO) accuracy with the MCFM 7.0 program [45].

The ggF H production process is simulated using the HJ-MINLO [35,46–48] event generator with mass $m_H = 125$ GeV and including finite top quark mass effects, following the recommendation in Ref. [48]. The POWHEG [49] generator is used to model the H production through the VBF, VH, and $t\bar{t}H$ processes [47,50,51].

For parton showering and hadronization, the POWHEG and MADGRAPH5_aMC@NLO samples are interfaced with PYTHIA8.205 (8.230) for 2016 (2017–2018) running conditions. The corresponding PYTHIA parameters for the underlying event description are set to the CUETP8M1 [52] (CP5 [53]) tune. For 2016 samples the parton distribution function (PDF) set NNPDF3.0 [54] is used, with either LO or NLO accuracy, corresponding to that used in the matrix element calculations, while for 2017–2018 samples NNPDF3.1 [55] at NNLO accuracy is used for all processes. The detector response is modeled with GEANT4 [56].

Reconstructed particles are clustered into jets using the anti-k_T algorithm [57,58]. Small-radius jets are clustered with a distance parameter of 0.4 (AK4 jets). Large-radius jets arising from the decays of boosted heavy particles are reconstructed with a distance parameter of 0.8 (AK8 jets). The effect of particles from additional proton-proton interactions within the same or nearby bunch crossings (pileup) is mitigated through the charged hadron subtraction [27] and pileup-per-particle identification [59] algorithms for AK4 and AK8 jets, respectively. Additional corrections are applied to the jet energy as functions of jet pseudorapidity (η) and p_T to account for the detector response.

The H candidate is reconstructed as a single AK8 jet with $p_T > 450$ GeV. A mix of triggers using jet p_T or a scalar sum of the jet p_T in the event is employed for online selection. At $p_T = 450$ GeV, the online selection is 90% efficient with respect to the offline selection, reaching full efficiency by 500 GeV. The soft-drop (SD) algorithm [60] with parameters $\beta = 0$ and $z = 0.1$ is applied to the jet mass (m_{SD}) to remove soft and wide-angle radiation, which reduces the mass of jets originating from QCD background events while preserving the mass of jets originating from heavy boson decays. The range of interest is set to $40 < m_{\text{SD}} < 201$ GeV. To match the tracker acceptance region, jets are required to have $|\eta| < 2.5$. In case of several jets in the event passing the criteria, the jet with the highest charm versus light tagging score, defined below, is taken to be the H candidate.

After the above selections, the dominant background is the QCD multijet production, which accounts for more than 95% of the expected yield and is estimated from data. The $V+$jets processes are significant resonant backgrounds at approximately 4%, and are estimated from simulation. The $t\bar{t}$ process constitutes a subdominant nonresonant background across the m_{SD} spectrum, the shape of which is taken from simulation, while the total yield is estimated from data. Other EW processes, including diboson, triboson, and $t\bar{t}V$ processes, are estimated from simulation and found to be negligible.

Events containing leptons are vetoed to reduce SM EW backgrounds. The selection criteria for electrons, muons, and hadronic τ leptons are $p_T > 10$, 10, and 20 GeV and $|\eta| < 2.5$, 2.4, and 2.3, along with "veto," "loose," and "very loose" identification requirements [24,28,61], respectively. In addition, muons are required to have a relative isolation (scalar p_T sum of the PF candidates within a cone with a distance parameter of 0.4, divided by the lepton p_T) of less than 0.25. Events with $p_T^{\text{miss}} > 140$ GeV, as well as events with AK4 b-tagged jets with $p_T > 30$ GeV opposite in azimuth to the H candidate jet [$\Delta\phi(\text{AK4}, \text{AK8}) > \pi/2$], are removed to reduce the top quark background. The AK4

b jet identification is performed using the DeepCSV DNN algorithm [62] with a working point corresponding to a 1% misidentification probability for light (u, d, s quark, or gluon) jets.

The dimensionless mass scale variable $\rho = 2\ln(m_{\mathrm{SD}}/p_T)$ [63,64] is used to parametrize the QCD background model (described below) as its distribution is approximately invariant versus jet p_T, unlike jet m_{SD}. A selection of $-6.0 < \rho < -2.1$ is imposed to avoid instabilities and edge effects from the SD algorithm and jet clustering [65]. The lower ρ threshold implies an upper jet p_T threshold, which is made explicit by requiring $p_T < 1200$ GeV. In simulation, less than 1% of signal events are found above this upper bound.

The N_2^1 variable [66], a ratio of energy correlation functions [67], is a powerful way to identify two-pronged signatures. However, using it for selection distorts the background jet mass distribution as a function of p_T. To mitigate this effect, the designing decorrelated taggers (DDT) technique [64], effectively a sliding selection, is applied. The selection is on $N_2^{1,\mathrm{DDT}} \equiv N_2^1 - q_{0.26}(p_T,\rho) < 0$, where $q_{0.26}(p_T,\rho)$ is the N_2^1 value corresponding to the 26% efficiency for the QCD background, as a function of jet p_T and ρ. The target percentile is chosen to optimize the $H \to c\bar{c}$ expected significance.

Finally, jet flavor is determined by the DeepDoubleX DNN algorithm [68]. The model comprises convolutional and recurrent units processing low-level features of secondary vertices and PF candidates, the outputs of which are joined with expert variables [62] in a fully connected layer. The application of feature importance ranking techniques, such as integrated gradients [69] and deep Taylor decomposition [70], indicates the key features to be the angular distances of the PF candidates from both the jet and 2-subjetiness [71] axes. The kinematic properties of the PF candidates defined relative to the parent jet have subleading importance. The model is trained to distinguish between two-pronged H-like signatures of bottom and charm flavors, as well as the QCD background, yielding two per-jet classifiers: charm versus light, referred to as DeepDoubleCvL (DDCvL), and charm versus bottom, referred to as DeepDoubleCvB (DDCvB). The performance of the two classifiers is shown, prior to any analysis-specific selection, in Fig. 1. The optimal working point, maximizing the $H \to c\bar{c}$ expected significance after all previous selections are applied, is found with respect to both classifiers at a QCD efficiency of 0.5% and a $H \to c\bar{c}$ efficiency of 20.6%. The corresponding efficiency for $H \to b\bar{b}$ events is 4.8%. As the classifiers are mass independent, the quoted efficiencies also apply to $Z \to c\bar{c}$ and $Z \to b\bar{b}$.

The relative contributions of H production modes to the overall signal yield are 55%, 25%, and 20% for

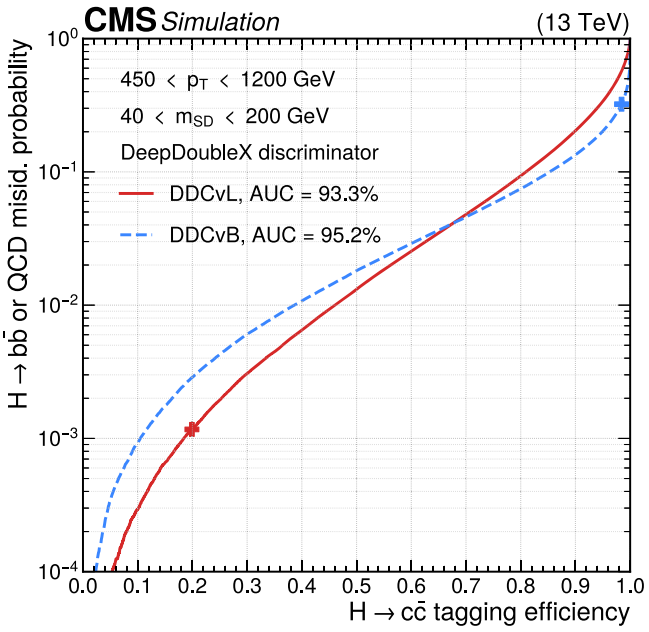

FIG. 1. The DDCvL and DDCvB performance for $H \to c\bar{c}$ identification versus QCD and $H \to b\bar{b}$ processes, respectively. No selection apart from the displayed m_{SD} and p_T requirements is applied. The working points used in this search are marked with a cross. The AUC is the area-under-curve metric.

ggF, VBF, and VH, respectively, and are similar for both $c\bar{c}$ and $b\bar{b}$ decay modes. The $t\bar{t}H$ contribution is suppressed due to the top veto and found to be negligible. Events passing all of the selection requirements described above constitute the signal or "passing" region (SR), whereas events failing the DDCvL requirement while passing the rest, including the DDCvB requirement, constitute the control or "failing" region (CR). Both the SR and CR are subdivided into 23 evenly spaced bins of jet m_{SD} in the range 40–201 GeV and 6 p_T bins from 450 (or 475) to 1200 GeV. Additionally, all regions are subdivided according to the three data-taking years (2016–2018).

The QCD background is not accurately predicted in simulation. Since the flavor discrimination is nearly independent of the jet p_T and mass, the ratio of the passing and failing region distributions, $R_{\mathrm{p/f}}$, is expected to be approximately flat with respect to the jet p_T and m_{SD}. This can be exploited to obtain an SR prediction of the QCD background from the CR via an appropriate efficiency scaling. A residual difference in shapes can be accounted for by parametrizing the $R_{\mathrm{p/f}}$ shape in the two dimensions. In order to take into account a potential mass dependence of the flavor selection efficiency, a correction factor, $R_{\mathrm{p/f}}^{\mathrm{QCD}}(p_T,\rho)$, is fit to the simulated QCD background shapes. Then, a second correction factor of the same functional form, $R^{\mathrm{data}}(p_T,\rho)$, accounts for mismodelings

in simulation. Both are parametrized in terms of Bernstein polynomials [72] in p_T and ρ:

$$R(p_T,\rho)=\sum_{k=0}^{n_\rho}\sum_{\ell=0}^{n_{p_T}} a_{k,\ell} b_{\ell,n_{p_T}}(p_T) b_{k,n_\rho}(\rho), \qquad (1)$$

where n_{p_T} is the degree of the polynomial in p_T, n_ρ is the degree of the polynomial in ρ, $a_{k,\ell}$ is a Bernstein coefficient, and $b_{\nu,n}$ is a Bernstein basis polynomial of degree n. The coefficients $a_{k,\ell}$ of $R^{\mathrm{QCD}}_{\mathrm{p/f}}(p_T,\rho)$ are determined in a fit to simulated QCD background events; $a_{k,\ell}$ of $R^{\mathrm{data}}_{\mathrm{p/f}}(p_T,\rho)$ are unconstrained and are determined during the maximum likelihood fit to data. The total effective $R_{\mathrm{p/f}}$ is then expressed as

$$R_{\mathrm{p/f}}(p_T,\rho)=R^{\mathrm{QCD}}_{\mathrm{p/f}}(p_T,\rho)R^{\mathrm{data}}(p_T,\rho). \qquad (2)$$

The $R_{\mathrm{p/f}}$ are expected to vary between data-taking years because of changes in detector conditions, and are thus fit independently for each year. The minimal degree of the polynomials necessary to fit the QCD simulation and the data is determined by a Fisher F-test [73] and found to be $(n_{p_T},n_\rho)=(0,2),(1,2)$, and (0, 2) for $R^{\mathrm{QCD}}_{\mathrm{p/f}}(p_T,\rho)$ and (1, 0), (0, 0), and (1, 0) for $R^{\mathrm{data}}(p_T,\rho)$ for the years 2016, 2017, and 2018, respectively. Bias tests were performed with respect to the choice of parametrization, and no significant bias was found.

The $V+$jets processes are modeled using simulation. The differential $t\bar{t}$ contribution is taken from simulation; however, the normalizations in the SR and CR are corrected via two scale factors measured in a dedicated $t\bar{t}$-enriched control region, parametrizing the overall normalization and the efficiency of the DDCvL selection between the SR and CR. This control region is adapted from the SR selection by lowering the H candidate p_T threshold, requiring exactly one muon, and inverting the selection requirements on $p_{\mathrm{T}}^{\mathrm{miss}}$ and b-tagged AK4 jets. The scale factor measurement is performed *in situ* during the signal extraction, separately for each data-taking period, and the values are given in Table I. The $H\to b\bar{b}$ contribution is taken from the simulation and is fixed to the SM expectation. While its expected SR yield is greater by approximately a factor of 5 than that of the $H\to c\bar{c}$ signal, its impact is negligible with respect to the overall background uncertainty.

The dominant systematic uncertainties for this search are related to the flavor tagging efficiency and jet mass shape. Corrections of the jet mass, jet mass resolution, and $N_2^{1,\mathrm{DDT}}$ and DDCvB efficiencies are derived from data using W boson jets from semileptonic $t\bar{t}$ events. These corrections are measured independently of jet flavor, and as such are correlated among all considered resonant (H, Z, W) production and decay processes. The DDCvL misidentification efficiency of the W process is measured here as well. The corrections and their associated uncertainties are given in Table I.

The efficiency of the DDCvL selection for the signal processes is estimated using data and simulation samples enriched in $c\bar{c}$ pairs from gluon splitting [62]. Signal-like events are selected by requiring each of the two SD subjets of an AK8 jet to contain a muon, targeting semileptonic decays of b/c hadrons. The efficiency is extracted from a template fit to the combined mass of all matched secondary vertices; the measured correction factors are given in Table I. The relative uncertainty of the misidentification efficiency of $b\bar{b}$ decays is assigned to be 30%. Varying this value from 10% to 50% has a negligible effect on reported results.

Other systematic uncertainties are assigned to cover potential mismodeling of the H signal, in particular for the ggF and VBF production modes [48], and higher-order corrections to the W and Z processes [44]. Finally, systematic uncertainties for experimental effects, including jet energy scale and resolution [74], trigger and veto efficiencies [75,76], variations in the measured pileup [77], finite simulated sample size [78], and an integrated luminosity measurement [79–81], are also included, but are found to have a comparatively small effect.

The parameter of interest in this analysis is the signal strength μ_H or μ_Z, defined as the ratio of the observed to the SM expected H or Z boson production cross section times the $H\to c\bar{c}$ or $Z\to c\bar{c}$ branching fraction, respectively. These parameters are extracted from a binned (m_{SD}, p_T) maximum likelihood fit to the observed data, where the expected value is the sum of the signal contribution (scaled by the signal strength parameter) and the background contributions, each modified by nuisance parameters to account for the previously discussed systematic effects. The magnitude of each systematic uncertainty is encoded in the likelihood model as an additional constraint, treated

TABLE I. Summary of the applied data-to-simulation scale factors for the jet mass, jet mass resolution, $N_2^{1,\mathrm{DDT}}$ selection, $t\bar{t}$ normalization, and DeepDoubleX selections for different data-taking periods. The jet mass correction is additive, in units of GeV.

Data period	Jet mass correction (GeV)	Jet mass resolution	$N_2^{1,\mathrm{DDT}}$, CvB selection	$t\bar{t}$ normalization	CvL selection $t\bar{t}$	CvL selection ($W+$jets)	CvL selection (signal)
2016	-1.17 ± 0.22	1.021 ± 0.017	0.89 ± 0.02	0.84 ± 0.05	0.93 ± 0.15	0.62 ± 0.09	1.15 ± 0.25
2017	-1.19 ± 0.23	1.019 ± 0.016	0.90 ± 0.02	0.86 ± 0.09	0.93 ± 0.15	0.64 ± 0.09	0.85 ± 0.16
2018	-0.12 ± 0.21	1.090 ± 0.031	0.92 ± 0.02	0.86 ± 0.08	1.00 ± 0.14	0.72 ± 0.08	0.74 ± 0.20

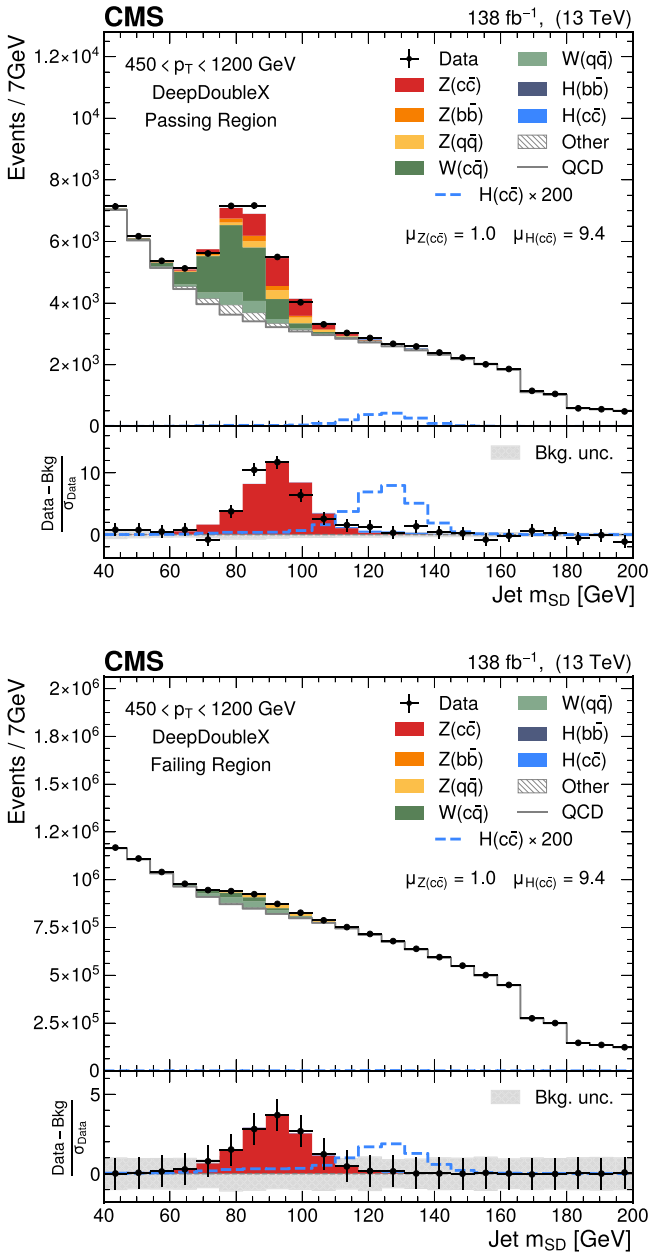

FIG. 2. The observed and fitted m_{SD} distributions for the passing (left) and failing (right) regions, combining all p_T categories and the three data-taking years. The fit is performed under the signal-plus-background hypothesis with a single inclusive $H \to c\bar{c}$ signal strength parameter. The $t\bar{t}$ background yields and the QCD background yields and shapes are estimated from data. The $t\bar{t}$ process constitutes the majority of contributions labeled "other." The dashed line represents the $H \to c\bar{c}$ expectation, multiplied by a factor of 200. The steplike features at 166 and 180 GeV are due to the ρ acceptance upper bound, which excludes bins with high m_{SD} and low p_T from the analysis. The lower panel shows the residual difference between the data and the overall background (excluding $Z \to c\bar{c}$), divided by the statistical uncertainty in the data. The near perfect model agreement with data in the failing region (right) is by construction.

according to the frequentist paradigm [82]. The fit is performed simultaneously across all subdivisions of the SR and CR described previously, as well as the per-year $t\bar{t}$ background enriched CRs.

To validate the analysis strategy, and to confirm the presence of $Z \to c\bar{c}$ decays, the Z signal strength μ_Z is measured via a profile likelihood fit, treating μ_H as a nuisance parameter, and is found to be $1.00^{+0.17}_{-0.14}(\text{syst}) \pm 0.08(\text{theo}) \pm 0.06(\text{stat})$. This corresponds to an excess, both observed and expected, over the $\mu_Z = 0$ hypothesis with a significance of well over 5 standard deviations. The precision of the μ_Z measurement is primarily limited by the systematic uncertainty in the DDCvL signal tagging efficiency. The subleading uncertainty comes from the modeling of the Z + jets production cross section.

For the extraction of μ_H, since the Z cross section has been measured in leptonic decay channels and found to agree with theoretical predictions within 5% in this p_T regime [83] and since the $Z \to c\bar{c}$ branching ratio is known to 2% precision [84], we fix $\mu_Z \equiv 1$, constraining the expected Z contribution to be within the applicable uncertainties of its SM value. This serves to further constrain *in situ* the DDCvL signal tagging efficiency uncertainty. The measured efficiencies are compatible with the values quoted in Table I and have approximately 30% lower uncertainty.

An observed (expected) upper limit is placed on the signal strength μ_H using the profile likelihood ratio test statistic [82], CL_s criterion [85,86], and asymptotic formulas [87], and found to be 47 (39) at 95% confidence level. For the best fit value of $\mu_H = 9.4^{+20.3}_{-19.9}$, the total m_{SD} distributions in the passing and failing regions are shown in Fig. 2, and a

TABLE II. Sources of uncertainty in the measurement of the signal strength $\mu_H = 9.4^{+20.3}_{-19.9}$, and their observed impact ($\Delta\mu_H$) in the fit to the full dataset. The impact of each uncertainty is evaluated by computing the uncertainty excluding that source and subtracting it in quadrature from the total uncertainty. The total uncertainty does not match the sum in quadrature of each source because of correlations among the components.

Uncertainty source	$\Delta\mu_H$

breakdown of the sources of uncertainty affecting the measurement is shown in Table II. Tabulated results are provided in the HEPData record for this analysis [88].

In conclusion, a search for standard model (SM) Z and Higgs bosons produced with transverse momenta greater than 450 GeV and decaying to charm quark-antiquark ($c\bar{c}$) pairs has been performed in a data sample corresponding to an integrated luminosity of 138 fb^{-1} at $\sqrt{s} = 13$ TeV. New algorithms based on deep neural networks have been developed to identify jets originating from charm quark pairs. The $Z \to c\bar{c}$ process is observed in association with jets at a hadron collider for the first time, with a signal strength of $1.00^{+0.19}_{-0.17}$ relative to the SM prediction. This observation establishes $Z \to c\bar{c}$ as an important reference for future $X \to c\bar{c}$ searches. An observed (expected) upper limit on the product of the Higgs boson production cross section and branching fraction to $c\bar{c}$ of 47 (39) times the SM expectation is set at 95% confidence level.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid and other centers for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES and BNSF (Bulgaria); CERN; CAS, MoST, and NSFC (China); MINCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); MoER, ERC PUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRI (Greece); NKFIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MES and NSC (Poland); FCT (Portugal); MESTD (Serbia); MCIN/AEI and PCTI (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); MHESI and NSTDA (Thailand); TUBITAK and TENMAK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

[182]Authors affiliated with an institute or an international laboratory covered by a cooperation agreement with CERN

[a]Deceased.
[b]Also at Yerevan State University, Yerevan, Armenia.
[c]Also at TU Wien, Vienna, Austria.
[d]Also at Institute of Basic and Applied Sciences, Faculty of Engineering, Arab Academy for Science, Technology and Maritime Transport, Alexandria, Egypt.
[e]Also at Université Libre de Bruxelles, Bruxelles, Belgium.
[f]Also at Universidade Estadual de Campinas, Campinas, Brazil.
[g]Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil.
[h]Also at UFMS, Nova Andradina, Brazil.
[i]Also at University of Chinese Academy of Sciences, Beijing, China.
[j]Also at Nanjing Normal University Department of Physics, Nanjing, China.
[k]Also at The University of Iowa, Iowa City, Iowa, USA.
[l]Also at University of Chinese Academy of Sciences, Beijing, China.
[m]Also at Another institute or international laboratory covered by a cooperation agreement with CERN.
[n]Also at British University in Egypt, Cairo, Egypt.
[o]Also at Suez University, Suez, Egypt.
[p]Also at Purdue University, West Lafayette, Indiana, USA.
[q]Also at Université de Haute Alsace, Mulhouse, France.
[r]Also at Department of Physics, Tsinghua University, Beijing, China.
[s]Also at The University of the State of Amazonas, Manaus, Brazil.
[t]Also at Erzincan Binali Yildirim University, Erzincan, Turkey.
[u]Also at University of Hamburg, Hamburg, Germany.
[v]Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany.
[w]Also at Isfahan University of Technology, Isfahan, Iran.
[x]Also at Bergische University Wuppertal (BUW), Wuppertal, Germany.
[y]Also at Brandenburg University of Technology, Cottbus, Germany.

[z]Also at Forschungszentrum Jülich, Juelich, Germany.
[aa]Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland.
[bb]Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt.
[cc]Also at Karoly Robert Campus, MATE Institute of Technology, Gyongyos, Hungary.
[dd]Also at Wigner Research Centre for Physics, Budapest, Hungary.
[ee]Also at Institute of Physics, University of Debrecen, Debrecen, Hungary.
[ff]Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.
[gg]Also at Universitatea Babes-Bolyai—Facultatea de Fizica, Cluj-Napoca, Romania.
[hh]Also at Faculty of Informatics, University of Debrecen, Debrecen, Hungary.
[ii]Also at Punjab Agricultural University, Ludhiana, India.
[jj]Also at UPES—University of Petroleum and Energy Studies, Dehradun, India.
[kk]Also at University of Visva-Bharati, Santiniketan, India.
[ll]Also at University of Hyderabad, Hyderabad, India.
[mm]Also at Indian Institute of Science (IISc), Bangalore, India.
[nn]Also at Indian Institute of Technology (IIT), Mumbai, India.
[oo]Also at IIT Bhubaneswar, Bhubaneswar, India.
[pp]Also at Institute of Physics, Bhubaneswar, India.
[qq]Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany.
[rr]Also at Sharif University of Technology, Tehran, Iran.
[ss]Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran.
[tt]Also at Helwan University, Cairo, Egypt.
[uu]Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy.
[vv]Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy.
[ww]Also at Università degli Studi Guglielmo Marconi, Roma, Italy.
[xx]Also at Scuola Superiore Meridionale, Università di Napoli 'Federico II', Napoli, Italy.
[yy]Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA.
[zz]Also at Università di Napoli 'Federico II', Napoli, Italy.
[aaa]Also at Ain Shams University, Cairo, Egypt.
[bbb]Also at Consiglio Nazionale delle Ricerche—Istituto Officina dei Materiali, Perugia, Italy.
[ccc]Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia.
[ddd]Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico.
[eee]Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France.
[fff]Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia.
[ggg]Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka.
[hhh]Also at INFN Sezione di Pavia, Università di Pavia, Pavia, Italy.
[iii]Also at National and Kapodistrian University of Athens, Athens, Greece.
[jjj]Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland.
[kkk]Also at Universität Zürich, Zurich, Switzerland.
[lll]Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria.
[mmm]Also at Laboratoire d'Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France.
[nnn]Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey.
[ooo]Also at Konya Technical University, Konya, Turkey.
[ppp]Also at Izmir Bakircay University, Izmir, Turkey.
[qqq]Also at Adiyaman University, Adiyaman, Turkey.
[rrr]Also at Istanbul Gedik University, Istanbul, Turkey.
[sss]Also at Necmettin Erbakan University, Konya, Turkey.
[ttt]Also at Bozok Universitetesi Rektörlügü, Yozgat, Turkey.
[uuu]Also at Marmara University, Istanbul, Turkey.
[vvv]Also at Milli Savunma University, Istanbul, Turkey.
[www]Also at Kafkas University, Kars, Turkey.
[xxx]Also at Hacettepe University, Ankara, Turkey.
[yyy]Also at Istanbul University—Cerrahpasa, Faculty of Engineering, Istanbul, Turkey.
[zzz]Also at Yildiz Technical University, Istanbul, Turkey.
[aaaa]Also at Vrije Universiteit Brussel, Brussel, Belgium.
[bbbb]Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
[cccc]Also at University of Bristol, Bristol, United Kingdom.
[dddd]Also at IPPP Durham University, Durham, United Kingdom.
[eeee]Also at Monash University, Faculty of Science, Clayton, Australia.
[ffff]Also at Università di Torino, Torino, Italy.
[gggg]Also at Bethel University, St. Paul, Minnesota, USA.

[hhhh]Also at Karamanoğlu Mehmetbey University, Karaman, Turkey.
[iiii]Also at California Institute of Technology, Pasadena, California, USA.
[jjjj]Also at United States Naval Academy, Annapolis, Maryland, USA.
[kkkk]Also at Bingol University, Bingol, Turkey.
[llll]Also at Georgian Technical University, Tbilisi, Georgia.
[mmmm]Also at Sinop University, Sinop, Turkey.
[nnnn]Also at Erciyes University, Kayseri, Turkey.
[oooo]Also at Texas A&M University at Qatar, Doha, Qatar.
[pppp]Also at Kyungpook National University, Daegu, Korea.
[qqqq]Also at Yerevan Physics Institute, Yerevan, Armenia.
[rrrr]Also at Imperial College, London, United Kingdom.
[ssss]Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.
