1. Introduction. Let $M$ be a complete smooth Riemannian manifold of dimension $n$ and $T_x M$ its tangent space at $x \in M$. Let $OM$ denote the space of orthonormal frames on $M$ and $\pi$ the projection that takes an orthonormal frame $u : \mathbb{R}^n \to T_x M$ to the point $x$ in $M$. Let $T_u \pi$ denote its differential at $u$. For $e \in \mathbb{R}^n$, let $H_u(e)$ be the basic horizontal vector field on $OM$ such that $T_u \pi(H_u(e)) = u(e)$, that is, $H_u(e)$ is the horizontal lift of the tangent vector $u(e)$ through $u$. If $\{e_i\}$ is an orthonormal basis of $\mathbb{R}^n$, the second-order differential operator $\Delta_H = \sum_{i=1}^n L_{H(e_i)}^2 L_{H(e_i)}$ is the Horizontal Laplacian. Let $\{w^i_t, 1 \leq i \leq n\}$ be a family of real valued independent Brownian motions. The solution $(u_t, t < \zeta)$, to the following semi-elliptic stochastic differential equation (SDE), $du_t = \sum_{i=1}^n H_{u_t}(e_i) \circ dw^i_t$, is a Markov process with infinitesimal generator $\frac{1}{2} \Delta_H$ and lifetime $\zeta$. We denote by $\circ$ Stratonovich integration. The solutions are known as horizontal Brownian motions. It is well known that a horizontal Brownian motion projects to a Brownian motion on $M$. We recall that a Brownian motion on $M$ is a sample continuous strong Markov process with generator $\frac{1}{2} \Delta$ where $\Delta$ is the Laplace–Beltrami operator. This construction of Brownian motions on a Riemannian manifold is canonical and has fundamental applications in analysis on path spaces.
For $e_0 \in \mathbb{R}^n$, the horizontal vector field $H(e_0)$ does not project to a vector field on $M$. It, however, induces a vector field $X$ on $TM$ which is a geodesic spray. If $(u^\varepsilon_t)$ is the solution to the first-order differential equation

$$\dot{u}(t) = H_{u(t)}(e_0), \quad u(0) = u_0,$$

then $\pi(u^\varepsilon_t)$ is the geodesic on $M$ with initial velocity $u_0(e_0)$ and initial value $\pi(u_0)$.

Let $N = \frac{n(n-1)}{2}$ and let $\mathfrak{so}(n)$ be the space of skew-symmetric matrices in dimension $n$. It is the Lie algebra of the orthogonal group $O(n)$. For $A \in \mathfrak{so}(n)$, we denote by $A^*$ the fundamental vertical vector field on $OM$ determined by right actions of the exponentials of $tA$; see (2.1) below. If $X$ is a vector field, we denote by $L_X$ Lie differentiation in the direction of $X$. Let us fix a time $T > 0$. Let $\rho$ be the Riemannian distance function on $M$, $\nabla$ the Levi–Civita connection and $\Delta$ the Laplace–Beltrami operator. Let $\varepsilon$ a positive number. Our main theorems concern the convergence, as $\varepsilon$ approaches zero, of the “horizontal part” of the solutions to a family of stochastic differential equations with parameter $\varepsilon$. The definitions for the horizontal and vertical vector fields and for the horizontal lift of a curve are given in Section 2. Let $e_0$ be a unit vector in $\mathbb{R}^n$.

**Theorem 1.1.** Let $M$ be a complete Riemannian manifold of dimension $n > 1$ and of positive injectivity radius. Suppose that there are positive numbers $C$ and a such that $\sup_{\rho(x,y) \leq a} |\nabla \rho|(x,y) \leq C$. Let $x_0 \in M$ and $u_0 \in \pi^{-1}(x_0)$. Let $\bar{A} \in \mathfrak{so}(n)$ and $\{A_1, \ldots, A_N\}$ be an orthonormal basis of $\mathfrak{so}(n)$. Let $(u^\varepsilon_t, 0 \leq t \leq T)$ be the solution to the SDE

$$\begin{cases}
\quad du^\varepsilon_t = H_{u^\varepsilon_t}(e_0) \, dt + \frac{1}{\sqrt{\varepsilon}} \sum_{k=1}^{N} A^*_k(u^\varepsilon_t) \circ dw^k_t + \bar{A}^*(u^\varepsilon_t) \, dt, \\
\quad u^\varepsilon_0 = u_0.
\end{cases}
$$

Let $x^\varepsilon_t = \pi(u^\varepsilon_t)$ and let $(\tilde{x}^\varepsilon_t, 0 \leq t \leq T)$ be the horizontal lift of $(x^\varepsilon_t, 0 \leq t \leq T)$ to $OM$ through $u_0$. Then the following statements hold:

1. The SDE does not explode.
2. The processes $(x^\varepsilon_t, 0 \leq t \leq T)$ and $(\tilde{x}^\varepsilon_t, 0 \leq t \leq T)$ converge in law, as $\varepsilon \to 0$.
3. The limiting law of $(x^\varepsilon_t, 0 \leq t \leq T)$ is independent of $e_0$. It is a scaled Brownian motion with generator $\frac{4}{n(n-1)} \Delta$. The limiting law of $(\tilde{x}^\varepsilon_t, 0 \leq t \leq T)$ is that associated to the generator $\frac{4}{n(n-1)} \Delta_H$.

If “$\varepsilon = \infty$” and $\bar{A} = 0$, the SDE (1.1) reduces to the first-order differential equation $\dot{u}(t) = H_{u(t)}(e_0)$ whose solutions are geodesics. If “$\varepsilon = 0$”, the SDE
“reduces” to the “vertical SDE”, \( du_t^\varepsilon = \frac{1}{\sqrt{\varepsilon}} \sum_{k=1}^{N} A_k^\varepsilon(u_t^\varepsilon) \circ dw_t^k \). This vertical equation does not have a meaning for \( \varepsilon = 0 \), nevertheless the “vertical SDE” has a first integral \( \pi : OM \to M \), that is, \( \pi(u_t^\varepsilon) = \pi(u_0^\varepsilon) \). By a preliminary multi-scale analysis, we see that \( \pi(u_t^\varepsilon) \) varies slowly with \( \varepsilon \) and there is a visible effective motion in the time interval \([0, \frac{1}{\varepsilon}]\). The first integral \( \pi \) is not a real-valued function. It is a function from a manifold to a manifold and the slow variables \( \{(x_t^\varepsilon), \varepsilon > 0\} \) are not Markov processes. Before further discussions on conservation laws related to the SDEs, we remark the following features: (1) the slow motion solves a first-order differential equation, (2) the “fast motion” on \( OM \) is not elliptic, (3) the limiting process is semi-elliptic. Another feature of Theorem 1.1 is that the pair of the intertwined family of stochastic processes \( (x_t^\varepsilon, \tilde{x}_t^\varepsilon) \) converge. We will explore (3) in a forthcoming article on homogeneous manifolds. For now, the following observation indicates a potential application of (3): the stochastic area of two linear Brownian motions \( \{w_1^t, w_2^t\} \) is the principal part of the horizontal lift of the two-dimensional Brownian motion \( \{w_1^t, w_2^t\} \) to the three-dimensional Heisenberg group. We remark also that the first-order horizontal geodesic equation on the orthonormal frame bundle corresponds a second-order differential equation on the manifold, which explains the unusual scaling in (1.1).

There have been many studies of limit theorems whose geometric settings or scalings or methodologies relate that in this article. For example, our philosophy agrees with that in Bismut [3] where the equation \( \ddot{x} = \frac{1}{T}(-\dot{x} + \dot{w}) \) interpolates between classical Brownian motion \( (T \to 0) \) and the geodesic flow \( (T \to \infty) \). In Ikeda [16] and Ikeda and Ochi [17], the authors studied limit theorems for line integrals of the form \( \int_0^T \phi(dx_s) \), where \( \phi \) is a differential form and \( (x_s) \) is a suitable process such as a Brownian motion. In Manabe and Ochi [23] the authors obtained central limit theorems for line integrals along geodesic flows. One of their tools is symbolic representations of geodesic flows. Another related work can be found in Pinsky [27], where a piecewise geodesic with a Poisson-type switching mechanism is shown to converge to the horizontal Brownian motion. We also note that geodesic flows perturbed by vertical Brownian motions were considered by Franchi and Le Jan [10], in the context of relativistic diffusions.

The conclusion of (1.1) is consistent with the following central limit theorems for geodesic flows. Let \( M \) be a manifold of constant negative curvature and of finite volume. Let \( (\gamma_t(x, v)) \) denote the geodesic with initial value \( (x, v) \) in the unit tangent bundle \( STM \) and let \( \theta_t(v) = (\gamma_t(x, v), \dot{\gamma}_t(x, v)) \), a stochastic process on \( STM \). Let \( f \) be a bounded measurable function on \( STM \) with the property that it is centered with respect to the normalized Liouville measure \( m \). Then there is a number \( \sigma \) with the property that

\[
\lim_{t \to \infty} m \left\{ \xi : \frac{\int_0^t f(\theta_s(\xi)) \, ds}{\sigma \sqrt{t}} \leq a \right\} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{a} e^{-y^2/2} \, dy.
\]
See Sinai [30], Ratner [28]; see Guivarch and Le Jan [12] and Enriquez, Franchi and Le Jan [8] for further developments. See also Helland [15] and Kipnis and Varadhan [19]. These results exploit the chaotic nature of the deterministic dynamical system on manifolds of negative curvature.

In the homogenisation literature, the following works are particularly relevant: Khasminskii [14, 18], Nelson [24], Borodin and Freidlin [4], Freidlin and Wentzell [11] and Bensoussan, Lions and Papanicolaou [1]. We note in particular Theorem 2.1 in [4] which deals with the convergence of path integrals of a suitable function along a family of ergodic Markov processes. In this article, such integrals are better understood as integrals of differential 1-forms along random paths. Finally, we mention the following work: Li [21] for averaging of integrable systems and Ruffino and Gonzales Gargate [29] for averaging on foliated manifolds. See also [22] for an earlier work on the orthonormal frame bundle. We also refer to Dowell [5] for a scaling limit of Ornstein–Uhlenbeck type.

**Open question.** The local uniform bound on $\nabla d\rho$ is only used in Lemma 3.2 for the proof of tightness. This bound can be weakened, for example, replaced by a local uniform control over the rate of growth of the norms of $\nabla d\rho$ and $\nabla \rho$. We remark that Brownian motion constructed in Theorem 1.1 is automatically complete. The conditions in Theorem 1.1 appear to be related to the uniform cover criterion on stochastic completeness and could be studied in connection with that in Li [20]. Also, much of the work in this article is valid for a connection $\nabla$ with torsion, the horizontal tangent bundle and $\Delta_H$ will then be induced by this connection with torsion. The effect of the torsion will generally lead to an additional drift to the Brownian motion downstairs. In this case the geodesic completeness of the manifold $M$ may no longer be equivalent to the metric completeness of $(M, \rho)$.

**2. Preliminaries.** Given a Riemannian metric on $M$, an orthonormal frame $u = \{u_1, \ldots, u_n\}$ is an ordered basis of $T_x M$ that is orthonormal. We denote by $OM$ the set of all orthonormal frames on $M$ and $\pi$ the map that takes the frame $u$ to the point $x \in M$. Let $\pi^{-1}(x) = \{u \in OM : \pi(u) = x\}$. If $(O, x)$ is a coordinate system on $M$, $u_i = \sum_j u^i_j \partial / \partial x^j|_x$. This gives a coordinate map on $OM$. The map $(x, u^i_j)$ is a homeomorphism from $\pi^{-1}(O)$ to $(x(O), O(n))$. If we identify a frame $u$ with the transformation $u: \mathbb{R}^n \to T_x M$, then $OM$ is a principal bundle with fibre $O(n)$ and group $G$, acting on the right. We adopt the notation $ue = u(e)$. For $g \in O(n)$ let $R_g$ denote right multiplication on $O(n)$ and the right action of $O(n)$ on $OM$. For $A, B \in \mathfrak{so}(n)$ let $\langle A, B \rangle = \text{tr} AB^T$.

A tangent vector $v$ in $OM$ is vertical if $T\pi(v) = 0$ where $T\pi$ denotes the differential of $\pi$. If $A$ belongs to the Lie algebra $\mathfrak{so}(n)$, we denote by $\exp(tA)$ the exponential map. If $u$ is a frame, the composition $u \exp(tA)$ is again
a frame in the same fibre. We define the fundamental vertical vector fields associated to $A$ by $A^*$,

\[(2.1) \quad A^*(u) = \frac{d}{dt} \bigg|_{t=0} u \exp(tA).\]

By a linear connection on the principal bundle $OM$, we mean a splitting of the tangent bundle $TOM$ with the following properties: (1) $T_uOM = HT_uOM \oplus VT_uOM$ (2) $(R_u)_*H_uTOM = H_uTOM$ for all $u \in OM$ and $a \in G$. The spaces $HT_uOM$ and $VT_uOM$ are, respectively, the horizontal tangent spaces and the vertical tangent spaces. We will introduce a metric on $OM$ such that $\pi$ is an isometry between $H_uTOM$ and $T_{\pi(u)}M$ and such that $H_uTOM$ and $VT_uOM$ are orthogonal. The metric on $\mathfrak{so}(n)$ is the bi-invariant metric introduced earlier. We will restrict our attention to the Levi–Civita connection.

Let $\mathfrak{h}_u(v)$ denote the horizontal lift of $v \in T_xM$ through $u \in \pi^{-1}(x)$. To each $e \in \mathbb{R}^n$ we denote $H_u(e) = \mathfrak{h}_u(ue)$ the basic vector field. Later, we also use $H_u(e)$ for $H_u(e)$. If $\{e_1, \ldots, e_n\}$ is an orthonormal basis of $\mathbb{R}^n$, then $\{H_u(e_1), \ldots, H_u(e_n)\}$ is an orthonormal basis for the horizontal tangent space $HT_uOM$.

A piecewise $C^1$ curve $\gamma$ on $OM$ is horizontal if the one-sided derivatives $\hat{\gamma}(\pm)$ are horizontal for all $t$. If $c$ is a $C^1$ curve on $M$, there is a horizontal curve $\tilde{c}$ on $OM$ such that $\tilde{c}$ covers $c$, that is, $\pi(\tilde{c}(t)) = c(t)$. In fact, $\tilde{c}(t)$ is the family of orthonormal frames along $c$ that are obtained by parallel transporting the frame $\tilde{0}$). We say that $\tilde{c}$ is a horizontal lift of $c$. The map $\tilde{c}(t)(\tilde{c}(0))^{-1}: T_{\tilde{c}(0)}M \to T_{\tilde{c}(t)}M$ is the parallel translation along the curve $c(t)$. In a coordinate chart $(O, x)$, the principal part of $\tilde{c}(t)$ is a $n \times n$ matrix whose column vectors $\{\tilde{c}_1(t), \ldots, \tilde{c}_n(t)\}$ form a frame. In components, write $\tilde{c}_i(t) = (\tilde{c}^1_i(t), \ldots, \tilde{c}^n_i(t))^T$. Then

$$\frac{\partial \tilde{c}^k_i(t)}{\partial t} + \sum_{i=1,j=1}^{n} \frac{\partial \tilde{c}^i(t)}{\partial t} \Gamma_{ij}^k(c(t))\tilde{c}^j_i(t) = 0.$$ 

Take $c(t) = (0, \ldots, t, \ldots, 0)$, where the nonzero entry is in the $i$th-place. We obtain the principal part of the horizontal lift of $\frac{\partial}{\partial x_i}$ through $u = \tilde{c}(0) = (u_i^j)$:

$$\left(\mathfrak{h}_u(0) \left( \frac{\partial}{\partial x_i} \right) \right)_l = \left( \frac{\partial \tilde{c}^i(t)}{\partial t} \right)_l = -\left( \sum_j \Gamma_{ij}^k u_j^i, \ldots, \sum_j \Gamma_{ij}^n u_j^n \right)^T.$$

Denote by $A_i$ the matrix whose element at the $(b, l)$ position is $\sum_j \Gamma_{ij}^b u_l^j$. Then $A_i$ is the principal part of $H_u(\frac{\partial}{\partial x_i})$ and the horizontal space at $u$ is spanned by the basis $\{(\frac{\partial}{\partial x_i}, A_i)\}$.
A basic object we use in our computation is the connection 1-form $\varpi$ on $OM$. A connection 1-form assigns a skew symmetric matrix to every tangent vector on $OM$ and it satisfies the following conditions:

1. $\varpi(A^*) = A$ for all $A \in \mathfrak{so}(n)$;
2. for all $a \in O(n)$ and $w \in OM$, $\varpi(R_a w) = Ad(a^{-1})\varpi(w)$. We recall that $R_a(A^*) = (Ad(a^{-1})A)^*$ for all $a \in O(n)$. It is convenient to consider horizontal tangent vectors on $OM$ as elements of the kernel of $\varpi$. If $\{A_1, \ldots, A_N\}$ is a basis of $\mathfrak{so}(n)$, then the horizontal component of a vector $w$ is $w^h = w - \sum_j \langle \varpi(w), A_j \rangle A_j^*$.

The connection 1-form $\varpi$ is basically the set of Christoffel symbols. Let $E = \{E_1, \ldots, E_n\}$ be a local frame; we define the Christoffel symbols relative to $E$ by $\nabla E_j = \sum_k \Gamma^k_{ij} dx_i \otimes E_k$. Let $\theta^i$ be the set of dual differential 1-forms on $M$ to $\{E_i\}$: $\theta^i(E_j) = \delta_{ij}$. We define $\omega_{ik}^j = \Gamma^j_{ik}$. Then $d\theta^i = -\sum_k \omega_{ik}^j \wedge \theta^k$. Let $\{A^*_j\}$ be a basis of $\mathfrak{g}$. To each moving frame $E$, we associate a 1-form, $\omega = \sum_{i,j} \omega_{ij}^i A^*_j$, on $OM$. If $(O, x)$ is a chart of $M$ and $s: O \to OM$ is a local section of $OM$, let us denote by $\omega_s$ the differential 1-form given above, then $\varpi(s^*v) = \omega_s(v)$. Conditions (1) and (2) are equivalent to the following: if $a: U \to G$ is a smooth function,

$$\varpi((s \cdot a)_* v) = a^{-1}(x) da(v) + a^{-1}(x)\varpi(s_* v) a(x).$$

This corresponds to the differentiation of $s \cdot a$ and this type of consideration will be used in the next section.

3. Some lemmas.

**Lemma 3.1.** Let $M$ be a geodesically complete Riemannian manifold. Let $(u^*_t)$ be the solution to the SDE (1.1) on $OM$. Let $\tilde{x}^*_t = \pi(u^*_t)$, which has a unique horizontal lift, $\tilde{x}^*_t$, through $u_0 \equiv u^*_0$. Then

$$\frac{d}{dt} \tilde{x}^*_t = \tilde{H}_{\tilde{x}^*_t}(g^*_t e_0),$$

$$dg^*_t = \frac{1}{\sqrt{\varepsilon}} \sum_{k=1}^m g^*_t A_k \circ dw^k_t + g^*_t \bar{\Omega} dt,$$

where $g^*_0$ is the unit matrix. Consequently the SDE (1.1) is conservative.

**Proof.** By the defining properties of the basic horizontal vector fields, $\dot{x}^*_t = \pi_* (HW^*_t(e_0)) = u^*_t e_0$. Let $h_u(v)$ denote the horizontal lift of a tangent vector $v$ through $u \in OM$. Since $u^*_t e_0$ has unit speed, the solution exists for all time if $(u^*_t)$ does, and

$$\frac{d}{dt} \tilde{x}^*_t = h_{\tilde{x}^*_t}(\tilde{x}^*_t) = h_{\tilde{x}^*_t}(u^*_t e_0).$$
At each time $t$, the horizontal lift $(\tilde{x}^\varepsilon_t)$ of the curve $(x^\varepsilon_t)$ through $u_0$ and the original curve $u_t$ belong to the same fibre. Let $g^\varepsilon_t$ be an element of $G$ with the property that $u^\varepsilon_t = \tilde{x}^\varepsilon_t g^\varepsilon_t$. Then $g^\varepsilon_0$ is the unit matrix and

$$\frac{d}{dt} \tilde{x}^\varepsilon_t = h_{\tilde{x}^\varepsilon_t} (\tilde{x}^\varepsilon_t g^\varepsilon_t e_0) = H_{\tilde{x}^\varepsilon_t} (g^\varepsilon_t e_0).$$

If $a_t$ is a $C^1$ path with values in $O(n)$, $a_t^{-1} \dot{a}_t = \frac{d}{dt}|_{r=0} e^{r a_t^{-1} \dot{a}_t}$, its action on $u$ gives rise to a fundamental vector field,

$$\frac{d}{dt} \bigg|_t u a_t = \frac{d}{dr} \bigg|_{r=0} u a_t a_t^{-1} a_{r+t} = (a_t^{-1} \dot{a}_t)^*(u a_t).$$

We denote by $DL_g$ and $DR_g$, respectively, the differentials of the left multiplication and of the right action. By Itô's formula applied to the product $\tilde{x}^\varepsilon_t g^\varepsilon_t$,

$$du^\varepsilon_t = DR_g^\varepsilon_t \circ d\tilde{x}^\varepsilon_t + (DL(g^\varepsilon_t)^{-1} \circ dg^\varepsilon_t)^*(u^\varepsilon_t).$$

Since right translation of horizontal vectors are horizontal, the connection 1-form vanishes on the first term and $\omega(\circ du^\varepsilon_t) = DL(g^\varepsilon_t)^{-1} \circ dg^\varepsilon_t$. We apply $\omega$ to the SDE for $u^\varepsilon_t$,

$$dg^\varepsilon_t = DL_g^\varepsilon_t \omega(\circ du^\varepsilon_t) = DL_g^\varepsilon_t \omega \left( \frac{1}{\sqrt{\varepsilon}} \sum_{k=1}^N A^*_k (u^\varepsilon_t) \circ dw^k_t + \tilde{A}^*(u^\varepsilon_t) dt \right)$$

$$= \frac{1}{\sqrt{\varepsilon}} \sum_{k=1}^m g^\varepsilon_t A_k \circ dw^k_t + g^\varepsilon_t \tilde{A} dt.$$

There is a global solution to the above equation. The ODE $\frac{d}{dt} \tilde{x}^\varepsilon_t = H_{\tilde{x}^\varepsilon_t} (g^\varepsilon_t e_0)$ has bounded right-hand side and has a global solution. It follows that $u^\varepsilon_t = \tilde{x}^\varepsilon_t g^\varepsilon_t$ has a global solution. \qed

**Remark 3.1.** Since the stochastic process $(g^\varepsilon_t)$ is sample continuous with initial value the unit matrix, it stays in the connected component $SO(n)$ of $O(n)$.

If $\{A_k\}$ is an orthonormal basis of $\mathfrak{so}(n)$ let $L_G = \frac{1}{2} \sum_{k=1}^N L_{gA_k} L_{gA_k}$. Then $(g^\varepsilon_t)$ is a Markov process with infinitesimal generator

$$L^\varepsilon = \frac{1}{\varepsilon} L_G + L_{gA}.$$

**Lemma 3.2.** Let $M$ be a complete Riemannian manifold with positive injectivity radius. Suppose that there are numbers $C > 0$ and $a_2 > 0$ such that $\sup_{\rho(x,y) \leq a_2} \| \nabla \rho \| (x,y) \leq C$. Let $T > 0$. The probability distributions of the family of stochastic processes $\{\tilde{x}^\varepsilon_t, t \leq T\}$ are tight. There is a metric $\tilde{d}$ on $M$ such that $\{(\tilde{x}^\varepsilon_t)\}$ is equi-Hölder continuous with exponent $\alpha < \frac{1}{2}$. 

Proof. Let \( \mu^\varepsilon \) be the probability laws of \( (\tilde{x}^\varepsilon_t) \) on the path space over \( OM \) with initial value \( u_0 \), which we denote by \( C([0,T]; OM) \). Since \( \tilde{x}^\varepsilon_0 = u_0 \), it suffices to estimate the modulus of continuity and show that for all positive numbers \( a, \eta \), there exists \( \delta > 0 \) such that for all \( \varepsilon \) sufficiently small (see Billingsley [2] and Ethier and Kurtz [9])

\[
P \left( \omega : \sup_{|s-t|<\delta} d(\tilde{x}^\varepsilon_t, \tilde{x}^\varepsilon_s) > a \right) < \delta \eta.
\]

Here, \( d \) denotes a distance function on \( OM \). We will choose a suitable distance function. The Riemannian distance function \( \tilde{\rho}(x, y) \) is not smooth in \( y \) if \( y \) is in the cut locus of \( x \). To avoid any assumption on the cut locus of \( OM \), we construct a new distance function that preserves the topology of \( OM \).

Let \( 2a \) be the minimum of \( 1, a_2 \) and the injectivity radius of \( M \). Let \( \phi : \mathbb{R}^+ \to \mathbb{R}^+ \) be a smooth concave function such that \( \phi(r) = r \) when \( r < a \) and \( \phi(r) = 1 \) when \( r \geq 2a \). Let \( \rho \) and \( \tilde{\rho} \) be, respectively, the Riemannian distance on \( M \) and on \( OM \). Then \( \phi \circ \rho \) and \( \tilde{d} = \phi \circ \tilde{\rho} \) are distance functions on \( M \) and on \( OM \), respectively. Then for \( r < t \),

\[
\phi^2 \circ \tilde{\rho}_{\varepsilon, s}(\tilde{x}^\varepsilon_t, \tilde{x}^\varepsilon_r) = \int_{r/\varepsilon}^{t/\varepsilon} D(\phi^2 \circ \tilde{\rho}_{\varepsilon, s})(H_{\tilde{x}^\varepsilon_s}(g_s^\varepsilon e_0)) ds.
\]

Since \( H_{\tilde{x}^\varepsilon_s}(g_s^\varepsilon e_0) \) has unit length, from the equation above we do not observe, directly, a uniform bound in \( \varepsilon \).

For further estimates, we work with a \( C^2 \) function \( F : OM \to \mathbb{R} \) to simplify the notation. Also, the computations below and some of the identities will be used later in the proof of Theorem 1.1. Let \( 0 \leq r < t \),

(3.1) \[
F(\tilde{x}^\varepsilon_t) = F(\tilde{x}^\varepsilon_r) + \int_{r/\varepsilon}^{t/\varepsilon} (DF)_{\tilde{x}^\varepsilon_s}(H_{\tilde{x}^\varepsilon_s}(g_s^\varepsilon e_0)) ds.
\]

Let \( \{e_i\} \) be an orthonormal basis of \( \mathbb{R}^n \). We define two sets of functions \( f_i : OM \to \mathbb{R} \) and \( h_i : O(n) \to \mathbb{R} \):

\[
f_i(u) = (DF)_u(H_u e_i), \quad \alpha_i(g) = \langle ge_0, e_i \rangle.
\]

From the linearity of \( H_u \), we obtain the identity \( H_u(ge_0) = \sum_{i=1}^n H_u(e_i) \alpha_i(u) \). Thus, the integrand in (3.1) factorizes and we have

(3.2) \[
F(\tilde{x}^\varepsilon_t) = F(\tilde{x}^\varepsilon_r) + \sum_{i=1}^n \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}^\varepsilon_s) \alpha_i(g_s^\varepsilon e_0) ds.
\]

Since the Riemannian metric on \( G = SO(n) \) is bi-invariant, the Riemannian volume measure, which locally has the form \( \sqrt{\det(g_{ij})} dx^1 \wedge \cdots \wedge dx^N \), is the Haar measure. Let \( dg \) be the Haar measure normalized to be a
probability measure on $G$. Let $\tilde{g}$ be a rotation such that $\tilde{g}e_0 = -e_0$. Then $\int_G g(\tilde{g}e_0) \, dg = \int_G g(e_0) \, dg$. The integral of $ge_0$ with respect to the Haar measure vanishes. In particular, $\int_G \alpha_0 \, dg = 0$. On a compact Riemannian manifold the Poisson equation with a smooth function that is centered with respect to the Riemannian volume measure has a unique centered smooth solution. For each $i$, let $h_i : G \to \mathbb{R}$ be the smooth centered solution to the Poisson equation

$$L_G h_i = \alpha_i = \langle ge_0, e_i \rangle.$$  

We apply Itô’s formula to the function $f_i h_i$ and $r < t$,

$$f_i(\tilde{x}_{t/\varepsilon}^\varepsilon) h_i(g_{t/\varepsilon}^\varepsilon) = f_i(\tilde{x}_{r/\varepsilon}^\varepsilon) h_i(g_{r/\varepsilon}^\varepsilon) + \int_{r/\varepsilon}^{t/\varepsilon} (Df_i)(\tilde{x}_s^\varepsilon)(H_{\tilde{x}_s^\varepsilon}(g_s^\varepsilon e_0)) h_i(g_s^\varepsilon) \, ds$$

$$+ \frac{1}{\sqrt{\varepsilon}} \sum_k \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}_s^\varepsilon)(Dh_i)(g_s^\varepsilon)(g_s^\varepsilon A_k) \, dw_s^k$$

$$+ \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}_s^\varepsilon) L_{g_s^\varepsilon A} h_i(g_s^\varepsilon) \, ds + \frac{1}{\varepsilon} \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}_s^\varepsilon) L_G h_i(g_s^\varepsilon) \, ds.$$  

We sum up the above equation from $i = 1$ to $n$. Note that

$$\sum_{i=1}^n f_i(u) L_G h_i(g) = \sum_{i=1}^n f_i(u) \alpha_i(g).$$  

We compare the last term in the above formula for $f_i(\tilde{x}_{t/\varepsilon}^\varepsilon) h_i(g_{t/\varepsilon}^\varepsilon)$ with the integral in (3.2) to obtain that

$$F(\tilde{x}_{t/\varepsilon}^\varepsilon) = F(\tilde{x}_{r/\varepsilon}^\varepsilon) + \varepsilon \sum_{i=1}^n (f_i(\tilde{x}_{t/\varepsilon}^\varepsilon) h_i(g_{t/\varepsilon}^\varepsilon) - f_i(\tilde{x}_{r/\varepsilon}^\varepsilon) h_i(g_{r/\varepsilon}^\varepsilon))$$

$$- \varepsilon \sum_{i=1}^n \int_{r/\varepsilon}^{t/\varepsilon} (Df_i)(\tilde{x}_s^\varepsilon)(H_{\tilde{x}_s^\varepsilon}(g_s^\varepsilon e_0)) h_i(g_s^\varepsilon) \, ds$$

$$- \varepsilon \sum_{i=1}^n \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}_s^\varepsilon) L_{g_s^\varepsilon A} h_i(g_s^\varepsilon) \, ds$$

$$- \sqrt{\varepsilon} \sum_{i=1}^n \sum_{k=1}^N \int_{r/\varepsilon}^{t/\varepsilon} f_i(\tilde{x}_s^\varepsilon)(Dh_i)(g_s^\varepsilon)(g_s^\varepsilon A_k) \, dw_s^k.$$  

Let us compute the differential of $f_i(u) = (DF)_u(H_u e_i)$. Let $\nabla$ be the flat connection on $OM$. It is determined by the parallelization $\nabla : OM \times \mathbb{R}^n \times \mathfrak{so}(n) \to TOM$ where $X_u(e, A) = H_u(e) + \pi_u^{-1}(A)$. In the calculation below,
we use the fact that $\nabla H(e) = 0$. 

$$F(\tilde{x}_{t/\varepsilon}^\varepsilon) - F(\tilde{x}_{r/\varepsilon}^\varepsilon)$$

$$= \varepsilon \sum_{i=1}^{n} ((DF)_{\tilde{x}_{t/\varepsilon}}(H_{\tilde{x}_{t/\varepsilon}^\varepsilon}g_i e_i)h_i(g_{t/\varepsilon}^\varepsilon) - (DF)_{\tilde{x}_{r/\varepsilon}}(H_{\tilde{x}_{r/\varepsilon}^\varepsilon}g_i e_i)h_i(g_{r/\varepsilon}^\varepsilon))$$

$$(3.4)$$

$$- \varepsilon \sum_{i=1}^{n} \int_{r/\varepsilon}^{t/\varepsilon} (\nabla DF)_{\tilde{x}_{s}^\varepsilon}(H_{\tilde{x}_{s}^\varepsilon}g_i e_i, H_{\tilde{x}_{s}^\varepsilon}e_i)h_i(g_{s}^\varepsilon) ds$$

$$- \varepsilon \sum_{i=1}^{n} \int_{r/\varepsilon}^{t/\varepsilon} (DF)_{\tilde{x}_{s}^\varepsilon}(H_{\tilde{x}_{s}^\varepsilon}e_i)L_{g_{s}^\varepsilon}A h_i(g_{s}^\varepsilon) ds$$

$$- \sqrt{\varepsilon} \sum_{i=1}^{n} \sum_{k=1}^{N} \int_{r/\varepsilon}^{t/\varepsilon} (DF)_{\tilde{x}_{s}^\varepsilon}(H_{\tilde{x}_{s}^\varepsilon}e_i)(Dh_i)_{(g_{s}^\varepsilon)}A_k dw_k.$$
The tightness of the law of \( \{ \tilde{x}_{t/\varepsilon}^\varepsilon \} \) follows. By Kolmogorov’s criterion, \( \{ \tilde{x}_{t/\varepsilon}^\varepsilon \} \) is Hölder continuous with exponent \( \alpha \) for any \( \alpha < \frac{1}{2} \). The Hölder constants are independent of \( \varepsilon \) and, for any \( p' < p \), Kolmogorov’s criterion yields

\[
\sup_{\varepsilon} \mathbb{E} \sup_{s \neq t} \left( \frac{\tilde{d}(\tilde{x}_{t/\varepsilon}^\varepsilon, \tilde{x}_{s/\varepsilon}^\varepsilon)}{|t - s|^\alpha} \right)^{p'} < \infty,
\]

thus completing the proof. \( \square \)

We will need the following lemma in which we make a statement on the limit of a function of two variables, one of which is ergodic and the other one varies significantly slower. The result is straightforward, but we include the proof for completeness. If \( f : N \to \mathbb{R} \) is a Lipschitz continuous function on a metric space \((N, d)\) with distance function \( d \), we denote by \(|f|_{\text{Lip}}\) its Lipschitz semi-norm. If \( S \) is a subset of \( N \), we let \( \text{Osc}_S(f) \) denote \( |\sup_{x \in S} f(x) - \inf_{x \in S} f(x)| \), the Oscillation of \( f \) over \( S \). Let \( \text{Osc}(f) = \text{Osc}_N(f) \).

Let \( E(N) \) be one of the following classes of real valued functions on a metric space \((N, d)\):

\[
E(N) = \{ f : N \to \mathbb{R} : |f|_{\text{Lip}} < \infty, \text{Osc}(f) < \infty \}
\]

or \( E_r(N) = E(N) \cap C^r \), where \( r = 0, 1, \ldots, \infty \). Denote

\[
|f|_E = |f|_{\text{Lip}} + \text{Osc}(f).
\]

Let \( d \) be the metric with respect to which the Lipschitz property is defined. We define \( \tilde{d} = d \wedge 1 \) to be a new metric on \( N \). Then \( |f|_{\text{Lip}} \leq C \) and \( \text{Osc}(f) \leq C \) is equivalent to \( f \) being Lipschitz with respect to \( \tilde{d} \).

Let \( p \geq 1 \) and let \( W^p_p(N) \) denote the Wasserstein \( p \)-distance between two probability measures on a metric space \((N, d)\):

\[
(W^p_p(\mu_1, \mu_2))^p = \inf_{\nu : (\nu_1, \nu_2) = (\mu_1, \mu_2)} \int_{N \times N} (d(x, y))^p d\nu(x, y).
\]

Let \( \mu_\varepsilon, \mu \) be a family of probability measures on the metric space \((N, d)\). Then \( \mu_\varepsilon \to \mu \) in \( W^p_p(N) \) if and only if they converge weakly and \( \sup_{x \in N} \int (d(x, y))^p d\mu_\varepsilon(y) \) is bounded for any \( x \in N \). If \( \tilde{d} = d \wedge 1 \), then \( \tilde{d} \) and \( d \) induce the same topology on \( N \) and the concepts of weak convergence are equivalent. With respect to \( \tilde{d} \), weak convergence is equivalent to Wasserstein \( p \)-convergence.

Let \((\Omega, \mathcal{F}, (\mathcal{F}_t), P)\) be a filtered probability space. Let \((Y, \rho), (Z, d)\) be metric spaces or \( C^m \) manifolds. Let \( \{(y^\varepsilon_t, t \leq T), \varepsilon > 0\} \) be a family of \( \mathcal{F}_t \)-adapted stochastic processes with state space \( Y \). Let \( (z^\varepsilon_t) \) be a family of sample continuous \( \mathcal{F}_t \)-Markov processes on \( Z \).
Assumption 3.3. (1) The stochastic processes \((y^{\varepsilon}_{t/\varepsilon}, t \leq T)\) are equi-
uniformly continuous and converge weakly to a continuous process \((\bar{y}_t, t \leq T)\).

(2) For each \(\varepsilon\), \((z^\varepsilon_{t/\varepsilon}, t \leq T)\) has an invariant measure \(\mu_{\varepsilon}\). There exists a function \(\delta\) on \(\mathbb{R}_+ \times Z \times \mathbb{R}_+\) with the property that \(\delta(\cdot, z, \varepsilon)\) is nondecreasing for each pair of \((z, \varepsilon)\) and \(\lim_{\varepsilon \to 0} \sup_{z \in Z} \delta(K, z, \varepsilon) = 0\) for all \(K\) and for all \(f \in E_r(Z)\) and \(t > 0\),

\[
\mathbb{E} \left[ \frac{\varepsilon}{t} \int_0^{t/\varepsilon} f(z^\varepsilon_{s/\varepsilon}) \, ds \right] \leq \int_Z f(z) \, d\mu_{\varepsilon}(z). \]

(3) There exists a probability measure \(\mu\) on \(W^1(C([0,T]; Z))\) s.t. \(\lim_{\varepsilon \to 0} W^1(\mu_{\varepsilon}, \mu) = 0\).

(4) The processes \((y^{\varepsilon}_{t/\varepsilon})\) converges to \((\bar{y}_t)\) in \(W^1(Y)\), and there exists an exponent \(\alpha > 0\) such that

\[
\sup_{\varepsilon} \mathbb{E} \left( \sup_{s \neq t} \rho(y^{\varepsilon}_{t/\varepsilon}, y^{\varepsilon}_{s/\varepsilon}) \right) < \infty.
\]

We cannot assume that \((\bar{y}_t)\) is adapted to the filtration with respect to which \((z^\varepsilon_{t/\varepsilon})\) is a Markov process. The process \((z^\varepsilon_{t/\varepsilon})\) is usually not convergent and we do not assume that \((y^{\varepsilon}_{t/\varepsilon}, z^\varepsilon_{t/\varepsilon})\) and \((\bar{y}_t)\) are realized in the same probability space.

We denote by \(\hat{P}_\eta\) the probability distribution of a random variable \(\eta\) and let \(T\) be a positive real number. If \(r\) is a positive number, let \(C([0,r]; Y)\) denote the space of continuous paths, \(\sigma: [0, r] \to Y\), on \(Y\). If \(F: C([0,r]; Y) \to \mathbb{R}\) is a Borel measurable function, we use the shorter notation \(F(y^{\varepsilon}_{t/\varepsilon})\) for \(F((u^{\varepsilon}_{t/\varepsilon}, u \leq r))\).

Lemma 3.4. Let \((\Omega, \mathcal{F}, (\mathcal{F}_t), P)\) be a filtered probability space. Let \((Y, \rho), (Z, d)\) be metric spaces or \(C^m\) manifolds in case \(m \geq 1\). Let \(\{y^{\varepsilon}_{t/\varepsilon}, t \leq T, \varepsilon > 0\}\) be a family of \(\mathcal{F}_t\)-adapted stochastic processes on \(Y\). Let \((z^\varepsilon_{t/\varepsilon})\) be a family of sample continuous \(\mathcal{F}_t\)-Markov processes on \(Z\). Let \(G \in E_r(Y \times Z)\). Let \(0 \leq r < t\) and let \(F: C([0,r]; Y) \to \mathbb{R}\) be a bounded continuous function. We define

\[
A(\varepsilon) \equiv A(\varepsilon, F, G) := F(y^{\varepsilon}_{t/\varepsilon}) \int_r^t G(y^{\varepsilon}_{s/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds.
\]

- If (1)–(3) in Assumption 3.3 hold, then the random variables \(A(\varepsilon)\) converge weakly to \(A\) as \(\varepsilon \to 0\), where

\[
A \equiv A(F, G) := F(\bar{y}_t) \int_r^t \int_Z G(\bar{y}_s, z) \, d\mu(z) \, ds.
\]
Assume (1)–(4) in Assumption 3.3. Then there is a constant c, s.t. for $\varepsilon < 1$,

$$W_1(\dot{P}_{\alpha(\varepsilon)}, \dot{P}_A) \leq c|F|_{\infty} \max_{z \in \mathbb{Z}} \delta \left( |G|_{E}, z, \frac{\varepsilon}{t - r} \right) + 2\varepsilon|F|_{\infty} \min (|G|_{\infty}, |\text{Osc}(G)|)$$

$$+ c(t - r)|F|_{\infty} |G|_{\text{Lip}} (W_1(\dot{P}_{y^\varepsilon}, \dot{P}_{\tilde{y}}) + W_1(\mu^\varepsilon, \mu)) + c\varepsilon^a |F|_{\infty} |G|_{\text{Lip}}.$$ 

PROOF. Let us fix the functions $F$, $G$, $r$, $t$ and define

$$\mathcal{E}_1(r, t) = \int_r^t G(y^\varepsilon_{s/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds - \int_r^t \int_{\mathbb{Z}} G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu_S(z) \, ds;$$

$$\mathcal{E}_2 = F(y^\varepsilon_{s/\varepsilon}) \left( \int_r^t \int_{\mathbb{Z}} G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu_S(z) \, ds - \int_r^t \int_{\mathbb{Z}} G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu(z) \, ds \right);$$

$$I(\varepsilon) = F(y^\varepsilon_{s/\varepsilon}) \int_r^t \int_{\mathbb{Z}} G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu(z) \, ds.$$ 

The proof is split into three parts: (i) $F(y^\varepsilon_{s/\varepsilon}) \mathcal{E}_1(r, t)$ converges to zero in $L_p(\Omega)$ for any $p > 1$, (ii) $\mathcal{E}_2$ converges to zero in $L_p(\Omega)$ for any $p > 1$ and (iii) $I(\varepsilon)$ converges to $A$ weakly.

We first prove that $F(y^\varepsilon([0, \frac{t}{\varepsilon}])) \mathcal{E}_1(r, t)$ converges to zero in $L_p(\Omega)$. Since $F$ is bounded it is sufficient to take $r = 0$ and $F$ a constant, and to work with $\mathcal{E}_1(0, t)$. Let us write

$$\mathcal{E}_1 := \int_0^t G(y^\varepsilon_{s/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds - \int_0^t \int_{\mathbb{Z}} G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu_S(z) \, ds.$$ 

Let $0 = t_0 < t_1 < \ldots < t_M \leq t$ be a partition of $[0, t]$ into pieces of size $t\varepsilon$. Let $M = M_\varepsilon = \lfloor \frac{t}{\varepsilon} \rfloor$. Let $\Delta t_i = t_{i+1} - t_i$ and let $\bar{t} = \varepsilon M_\varepsilon$. Below $a \sim b$ indicates “$a - b = O(\varepsilon)$” as $\varepsilon$ converges to 0. Since $G \in E_{m}(\mathbb{Y} \times \mathbb{Z})$,

$$|\mathcal{E}_1(\bar{t}, t)| \leq 2 \min \left( |G|_{\infty}, \text{Osc}(G), |G|_{\text{Lip}} \max_{0 \leq s \leq t} \int_{\mathbb{Z}} d(z^\varepsilon_{s/\varepsilon}, z) \mu_S(dz) \right) \left( t - \bar{t} \right)$$

$$\leq \varepsilon 2 \min (|G|_{\infty}, |\text{Osc}(G)|) \leq 2\varepsilon(|G|_{E}).$$ 

By the Lipschitz continuity of $G$, for each $\varepsilon > 0$ the following holds:

$$\mathcal{E}_3 := \left| \sum_{i=0}^{M_\varepsilon-1} \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{s/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds - \sum_{i=0}^{M_\varepsilon-1} \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{s/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds \right|$$

$$\leq |G|_{\text{Lip}} \sum_{i=0}^{M_\varepsilon-1} \int_{t_i}^{t_{i+1}} \rho(y^\varepsilon_{s/\varepsilon}, y^\varepsilon_{t/\varepsilon}) \, ds.$$
By equi-uniform continuity of \((y^\varepsilon_{s/\varepsilon})\), for almost surely all \(\omega\), \(\mathcal{E}_3\) converges to zero. Since \(\mathcal{E}_3\) is bounded the convergence is in \(L^p(\Omega)\). If \((y^\varepsilon_{s/\varepsilon})\) is assumed to be equi-Hölder continuous as in condition (4), there is a convergence rate of \(\varepsilon^{\alpha}|G|_{\text{Lip}}\) for the \(L^p\) convergence.

We prove next that \(\sum_{i=0}^{M-1} \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{t_i/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds\) converges. We apply the Markov property of \((z^\varepsilon_t)\) and we use the fact that \((y^\varepsilon_t)\) is adapted to the filtration \((\mathcal{F}_t)\), with respect to which \((z^\varepsilon_t)\) is a Markov process:

\[
\sum_{i=1}^{M-1} \mathbb{E} \left| \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{t_i/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds - \Delta t_i \int Z G(y^\varepsilon_{t_i/\varepsilon}, z) \, d\mu(z) \right|
\leq \sum_{i=1}^{M-1} \Delta t_i \mathbb{E} \left( \frac{1}{\Delta t_i} \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{t_i/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds \right.
\left. - \int Z G(y^\varepsilon_{t_i/\varepsilon}, z) \, d\mu(z) \right|_{y=y^\varepsilon_{t_i/\varepsilon}} \bigg|
\leq \sum_{i=1}^{M-1} \Delta t_i \mathbb{E} \left( \frac{\varepsilon^2}{\Delta t_i} \int_{t_i/\varepsilon^2}^{t_{i+1}/\varepsilon^2} G(y, z^\varepsilon_{s/\varepsilon}) \, ds \right.
\left. - \int Z G(y, z) \, d\mu(z) \right|_{y=y^\varepsilon_{t_i/\varepsilon}}
\right).
\]

Since \(\frac{\varepsilon^2}{\Delta t_i} = \frac{\varepsilon}{t_i}\), we may now apply condition (2) and obtain

\[
\mathbb{E} \left( \frac{\varepsilon^2}{\Delta t_i} \int_{t_i/\varepsilon^2}^{t_{i+1}/\varepsilon^2} G(y, z^\varepsilon_{s/\varepsilon}) \, ds - \int Z G(y, z) \, d\mu(z) \right) \leq \delta \left( |G|_{E, z^\varepsilon_{t_i/\varepsilon}, \frac{\varepsilon}{t_i}} \right).
\]

We record that

\[
\mathcal{E}_4 := \mathbb{E} \left| \sum_{i=0}^{M-1} \int_{t_i}^{t_{i+1}} G(y^\varepsilon_{t_i/\varepsilon}, z^\varepsilon_{s/\varepsilon}) \, ds - \sum_{i=0}^{M-1} \Delta t_i \int Z G(y^\varepsilon_{t_i/\varepsilon}, z) \, d\mu(z) \right|
\leq \max_{z \in Z} \delta \left( |G|_{E, z, \frac{\varepsilon}{t}} \right).
\] (3.6)

Let us define

\[
\mathcal{E}_5 := \sum_{i=0}^{M-1} \Delta t_i \int Z G(y^\varepsilon_{t_i/\varepsilon}, z) \, d\mu(z) - \int_0^t \int Z G(y^\varepsilon_{s/\varepsilon}, z) \, d\mu(z) \, ds.
\]
By the definition of Riemann integral
\[ \mathcal{E}_5 \leq |G|_{\text{Lip}} \sum_{i=0}^{M \varepsilon - 1} \Delta t_i \text{Osc}_{[s_i, s_{i+1}]}(y_{s/\varepsilon}^\varepsilon), \]

where \( \text{Osc}_{[a,b]}(f) \) denotes the oscillation of a function \( f \) in the indicated interval. Since \((y_{s/\varepsilon}^\varepsilon)\) is equi-uniform continuous on \([0,T]\), \( \mathcal{E}_5 \to 0 \) in \( L_p \). Given Hölder continuity of \((y_{s/\varepsilon}^\varepsilon)\) from condition (4), we have the quantitative estimates:
\[ |\mathcal{E}_5|_{L_p(\Omega)} \leq C |G|_{\text{Lip}} \varepsilon^\alpha. \]
To summarize,
\[ |\mathcal{E}_1(0,t)| \leq |\mathcal{E}_1(\tilde{t},t)| + \mathcal{E}_3 + \mathcal{E}_4 + \mathcal{E}_5. \]

It follows that \( F(y_{r/\varepsilon}^\varepsilon) \mathcal{E}_1(r,t) \) converges to zero.

When condition (4) holds, there is a constant \( C \) such that
\begin{equation}
|F(y_{r/\varepsilon}^\varepsilon) \mathcal{E}_1(r,t)|_{L_p(\Omega)} \\
\leq |F|_\infty (2\varepsilon \min(|G|_\infty, |\text{Osc}(G)|) + \mathcal{E}_3 + \mathcal{E}_4 + \mathcal{E}_5)
\end{equation}
\[ \leq C |F|_\infty (\varepsilon^\alpha + \varepsilon) |G|_{\text{Lip}} + 2\varepsilon |F|_\infty \min(|G|_\infty, |\text{Osc}(G)|)
\]
\[ + C |F|_\infty \max_{z \in \mathcal{Z}} \delta \left( |G|_{E, z}, \frac{\varepsilon}{t-r} \right). \]

For any two random variables on the same probability space and with the same state space, the \( L_p \) norm of their difference dominates their Wasserstein \( p \)-distance. The random variable
\[ F(y_{r/\varepsilon}^\varepsilon) \int_r^t G(y_{s/\varepsilon}^\varepsilon, z) \, d\mu_{\varepsilon}(z) \, ds \]
with the same rate as indicated above.

We proceed to step (ii). It is clear that for almost all \( \omega \), \( F(y_{r/\varepsilon}^\varepsilon) \int_r^t G(y_{s/\varepsilon}^\varepsilon, z) \, ds \)
is Lipschitz continuous in \( z \). For any \( z_1, z_2 \in \mathcal{Z} \),
\[ \left| F(y_{r/\varepsilon}^\varepsilon) \int_r^t G(y_{s/\varepsilon}^\varepsilon, z_1) \, ds - F(y_{r/\varepsilon}^\varepsilon) \int_r^t G(y_{s/\varepsilon}^\varepsilon, z_2) \, ds \right| \\
\leq |F|_\infty d(z_1, z_2) \int_r^t |G(y_{s/\varepsilon}^\varepsilon, \cdot)|_{\text{Lip}} \, ds \leq (t-r) d(z_1, z_2) |F|_\infty |G|_{\text{Lip}}. \]

By the Kantorovich duality formula, for the distance between two probability measures \( \mu_1 \) and \( \mu_2 \),
\[ W_1(\mu_1, \mu_2) = \sup \left\{ \int U \, d\mu_1 - \int U \, d\mu_2 : |U|_{\text{Lip}} \leq 1 \right\}, \]
we have
\[ |\mathcal{E}_2| \leq (t-r) \cdot |F|_\infty \cdot |G|_{\text{Lip}} \cdot W_1(\mu^\varepsilon, \mu). \]
For part (iii), let \( U \) be a continuous function on \( C([0,T];Y) \). If \( \sigma \in C([0,T];Y) \), let us denote by \( \sigma([0,r]) \) the restriction of the path to \([0,r]\). Since \( F \) is bounded continuous and \( G \) is Lipschitz continuous,

\[
\sigma \mapsto U \left( F(\sigma([0,r])) \left( \int_r^t \int_Z G(\sigma_s, z) \, d\mu(z) \, ds \right) \right)
\]

is a continuous function on \( C([0,T];Y) \). By the weak convergence of \( (y^\varepsilon_{y/\varepsilon}) \), \( \mathbb{E}(U(I(\varepsilon))) \) converges to \( \mathbb{E}(U(A(F,G))) \) and the random variables \( I(\varepsilon) \) converge weakly to \( A(F,G) \). By now, we have proved that \( A(\varepsilon,F,G) \) converges to \( A(F,G) \) weakly; we thus conclude the first part of the lemma.

Let us assume condition (4) from Assumption 3.3. In particular, \( (y^\varepsilon_{y/\varepsilon}) \) converges in \( W_1(C([0,T];Y)) \). Let \( U \) be a Lipschitz continuous function on \( C([0,T];Y) \). We define \( \bar{U}:C([0,T];Y) \to \mathbb{R} \) by

\[
\bar{U}(\sigma) = U \left( F(\sigma([0,r])) \left( \int_r^t \int_Z G(\sigma_s, z) \, d\mu(z) \, ds \right) \right).
\]

Let \( \sigma^1, \sigma^2 \) are two paths on \( Y \),

\[
|\bar{U}(\sigma_1) - \bar{U}(\sigma_2)| \\
\leq |U|_{\text{Lip}} \cdot |F|_{\infty} \left| \int_r^t \int_Z G(\sigma^1_s, z) \, d\mu(z) \, ds - \int_r^t \int_Z G(\sigma^2_s, z) \, d\mu(z) \, ds \right| \\
\leq (t - r)|U|_{\text{Lip}} \cdot |F|_{\infty} \cdot |G|_{\text{Lip}} \cdot \sup_{0 \leq s \leq T} \rho(\sigma^1_s, \sigma^2_s).
\]

By the Kantorovich duality and assumption (4),

\[
W_1(\hat{P}_t(\varepsilon), \hat{P}_1) \leq (t - r) \cdot |F|_{\infty} \cdot |G|_{\text{Lip}} \cdot W_1(\hat{P}_{y/\varepsilon}, \hat{P}_{y}).
\]

We collect all the estimations together. Under assumptions (1)–(4), the following estimates hold:

\[
W_1(\hat{P}_{A(\varepsilon)}, \hat{P}_A) \leq C|F|_{\infty}|G|_{\text{Lip}}(\varepsilon^\alpha + \varepsilon) + C|F|_{\infty} \max_{z \in Z} \delta \left( |G|_{E}, z, \frac{\varepsilon}{t - r} \right) \\
+ C(t - r) \cdot |F|_{\infty} \cdot |G|_{\text{Lip}} \cdot W_1(\hat{P}_{y/\varepsilon}, \hat{P}_y) + W_1(\mu_\varepsilon, \mu) \\
+ 2\varepsilon|F|_{\infty} \min(|G|_{\infty}, |\text{Osc}(G)|).
\]

We may now limit ourselves to \( \varepsilon \leq 1 \) and conclude part 2 of the lemma.

**Remark 3.2.** In the lemma above, we should really think that the \( z^\varepsilon \) process and process \( y^\varepsilon \) follow different clocks, the former is run at the fast time scale \( \frac{1}{\varepsilon} \) and the latter at scale 1.
Example 3.5. Let \((g_s)\) be a Brownian motion on \(G = SO(n)\), solving
\[
dg_t = \sum_{k=1}^{N} L_{g_t A_k} dw_t^k.
\]
Here, \(\{A_1, \ldots, A_N\}\) is an orthonormal basis of \(\mathfrak{g}\). In Lemma 3.4 we take \(z_t = g_t / \epsilon\), then condition (2) holds. If \(f\) is a Lipschitz continuous function, it is well known that the law of large numbers holds for \(\int_0^t f(g_s) \, ds\), so does a central limit theorem. The remainder term in the central limit theorem is of order \(\sqrt{t}\) and depends on \(f\) only through the Lipschitz constant \(|f|_{\text{Lip}}\).

It is easy to see that the remainder term in the law of large numbers depends only on the Lipschitz constant of the function. Without loss of generality, we assume that \(\int f \, dg = 0\). Let \(\alpha\) solve the Poisson equation:
\[
\Delta^G \alpha = f.
\]
Then
\[
\frac{1}{t} \int_0^t f(g_s) \, ds = \frac{1}{t} \alpha(g_t) - \frac{1}{t} \alpha(g_0) - \sum_k \int_0^t (D\alpha)(g_s A_k) \, dw_s^k.
\]

Since \(\alpha\) is bounded, we are only concerned with the martingale term. By Burkholder–Davis–Gundy inequality, its \(L^2\) norm is bounded by
\[
2 \left( \frac{1}{t} \sum_{k=1}^{N} \int_0^t \mathbb{E}((D\alpha)(g_s A_k))^2 \, ds \right)^{1/2} \leq 2 \left( \int_0^t \mathbb{E}|D\alpha|_{g_s}^2 \, ds \right)^{1/2}.
\]

By elliptic estimates, \(|D\alpha|\) is bounded by \(|f|_{\text{Lip}}\). Since \(f\) is centered, it is bounded by \(\text{Osc}(f)\). In summary,
\[
\mathbb{E} \left( \frac{1}{t} \int_0^t f(g_s) \, ds - \int_0^N f(g) \, dg \right)^2 \leq C(\text{Osc}(f) t^{-1/2})^2.
\]

In Theorem 1.1, we may wish to add an extra drift of the form \(\frac{1}{2} A^*\) where \(A \in \mathfrak{g}\), so that \(L_G + L_{g A}\). Translations by orthogonal matrices are isometries, so for any \(A \in \mathfrak{g}\) the vector field \(g A\) is a killing field, and the Haar measure remains an invariant measure for the diffusion with infinitesimal generator \(\frac{1}{2} \Delta^G + L_{g A}\). However, on a compact Lie group no left invariant vector field is the gradient of a function and \(\frac{1}{2} \Delta^G + L_{g A}\) is no longer a symmetric operator. In this case, we do not know how to obtain the estimate in the example.

4. Proof. We are ready to prove the main theorem. In Lemma 3.2, we used a fundamental technique to split the integral
\[
\int_{t/\epsilon}^{t/\epsilon} (DF)_{x_s} (H_{x_s}^*)(g_s e_0) \, ds
\]
into the sum of a process of finite variation and a martingale. The computation in the proof of Lemma 3.2 will be used to prove the weak convergence. A similar consideration was used in Li [21], which was inspired by a paper of Hairer and Pavliotis [13]. In the above-mentioned papers, the convergence is in probability; while here we can only expect weak convergence.

To prove the convergence, we apply Stroock–Varadhan’s martingale method and Lemma 3.4; see also Borodin and Freidlin [4]; Papanicolaou, Stroock and Varadhan [25, 26] where the limit is given by a double integration in time. Our formulation for the limit is in terms of space averaging. Finally, we use explicit eigenfunctions of the Laplacian on $SO(n)$ to compute the limiting generator.

**Proof of Theorem 1.1.** We define a Markov generator $\bar{L}$ on $OM$. If $F: OM \to \mathbb{R}$ is bounded and Borel measurable and $\{e_i\}$ is an orthonormal basis of $\mathbb{R}^n$, we define

$$\bar{L}F = -\sum_{i=1}^{n} \int_G (\nabla DF)_u (H_u(g e_0), H_u(e_i)) h_i(g) \, dg$$

(4.1)

$$-\sum_{i=1}^{n} \int_G (DF)_u (H_u e_i) L g h_i(g) \, dg,$$

where $h_i$ is the solution to the Poisson equation (3.3). Since $(\bar{x}_{t/\varepsilon}^\varepsilon)$ is tight by Lemma 3.2, every sub-sequence of $(\bar{x}_{t/\varepsilon}^\varepsilon)$ has a sub-sequence that converges in distribution. We will prove that the probability distributions of $(\bar{x}_{t/\varepsilon}^\varepsilon)$ converge weakly to the probability measure, $\bar{P}$, determined by $\bar{L}$. It is sufficient to prove that if $(\bar{y}_t)$ is a limit of $(\bar{x}_{t/\varepsilon}^\varepsilon)$, then

$$F(\bar{y}_t) - F(u_0) - \int_0^t \bar{L}F(\bar{y}_s) \, ds$$

is a martingale. Since the convergence is weak, and the Markov process $(\bar{x}_{t/\varepsilon}^\varepsilon, \bar{g}_{t/\varepsilon}^\varepsilon)$ is not tight, we do not have a suitable filtration on $\Omega$ to work with. We formulate the above convergence on the space of continuous paths over $OM$ on a given time interval $[0, T]$.

Let $X_t$ be the coordinate process on the path space over $OM$, $\mathcal{G}_t = \sigma\{X_s : 0 \leq s \leq t\}$ and let $\bar{P}_{\bar{x}^\varepsilon}$ be the probability distribution of $(\bar{x}_{t/\varepsilon}^\varepsilon)$ on the path space over $OM$. By taking a subsequence if necessary, we may assume that $\{\bar{P}_{\bar{x}^\varepsilon}\}$ converges to $\bar{P}$.

Let $F: OM \to \mathbb{R}$ be a smooth function with compact support. We will prove that with respect to $\bar{P}$,

$$E\left\{ F(X_t) - F(X_r) - \int_r^t \bar{L}F(X_s) \, ds \bigg| \mathcal{G}_r \right\} = 0.$$
Since $\hat{P}_\varepsilon \to \bar{P}$ weakly, we only need to prove that for all bounded and continuous real value random variables $\xi$ that are measurable with respect to $\mathcal{G}_r$,

$$\lim_{\varepsilon \to 0} \int \xi(F(x_t) - F(x_r)) d\hat{P}_\varepsilon = \int \left( \xi \int_t^r \mathcal{L}F(X_s) ds \right) d\bar{P}. \tag{4.2}$$

By formula (3.4) in the proof of Lemma 3.2, for $t \geq r$,

$$F(x_{t/\varepsilon}) - F(x_{r/\varepsilon}) \sim -\varepsilon \sum_{i=1}^n \int_{t/\varepsilon}^{t/\varepsilon} (\nabla DF)_{x_{s/\varepsilon}}(H_{x_{s/\varepsilon}}(g_{s}^\varepsilon e_i), H_{x_{s/\varepsilon}}(e_{i}))h_i(g_s^\varepsilon) ds \tag{4.3}$$

$$-\varepsilon \sum_{i=1}^n \int_{t/\varepsilon}^{t/\varepsilon} (DF)_{x_{s/\varepsilon}}(H_{x_{s/\varepsilon}}(e_i))L_{g_s^\varepsilon}A_i h_i(g_{s}^\varepsilon) ds$$

$$-\sqrt{\varepsilon} \sum_{i=1}^n \sum_{k=1}^n \int_{t/\varepsilon}^{t/\varepsilon} (DF)_{x_{s/\varepsilon}}(H_{x_{s/\varepsilon}}(e_i))(Dh_i)(g_s^\varepsilon)(g_{s}^\varepsilon A_k) d\nu^k_i.$$  

Hence, up to a term of order $\varepsilon$,

$$\int \xi(F(x_t) - F(x_r)) d\hat{P}_\varepsilon$$

$$= O(\varepsilon) - \varepsilon \sum_{i=1}^n \int \left( \xi \int_{t/\varepsilon}^{t/\varepsilon} (\nabla DF)_{x_{s/\varepsilon}}(H_{X_s}(G_s e_0), H_{X_s}(e_i))h_i(G_s) ds \right) d\hat{P}_\varepsilon$$

$$-\varepsilon \sum_{i=1}^n \int \left( \xi \int_{t/\varepsilon}^{t/\varepsilon} (DF)_{x_{s/\varepsilon}}(H_{X_s}(e_i))L_{G_s}A_i h_i(G_s) ds \right) d\hat{P}_\varepsilon.$$

We prove this by working with the original processes. Let $(\bar{x}_{t})$ denote a subsequence of the original sequence with limit $(\bar{y}_s)$. For each $i, l = 1, \ldots, n$, let us define

$$\beta_i(u) = (\nabla DF)_{u}(H_u(e_i), H_u(e_i)).$$

By linearity of $H_u$ and $\nabla DF$,

$$(\nabla DF)_u(H_u(g_{e_0}), H_u(e_i))h_i(g)$$

$$= \sum_{l=1}^n (\nabla DF)_u(H_u(e_l), H_u(e_l))(g_{e_0}, e_l)h_i(g) = \sum_{l=1}^n \beta_i(u)(g_{e_0}, e_l)h_i(g),$$

for each $i = 1, \ldots, n$; and

$$-\varepsilon \int_{t/\varepsilon}^{t/\varepsilon} (\nabla DF)_{x_{s/\varepsilon}}(H_{x_{s/\varepsilon}}(g_{s}^\varepsilon e_0), H_{x_{s/\varepsilon}}(e_i))h_i(g_{s}^\varepsilon) ds.$$
We observe that \((g_{s_{\varepsilon}})\) satisfies the equation \(dg_t = \sum_k g_t A_k \circ dw_k^{\varepsilon}\) with initial value the identity element. The solution stays in the connected component \(SO(n)\). It is ergodic with the normalized Haar measure \(dg\) on \(SO(n)\) as its invariant measure and it satisfies the Birkhoff ergodic theorem; see Example 3.5. By Lemma 3.2, \((x_{s_{\varepsilon}})\) is tight, and equi-uniformly Hölder continuous on \([0,T]\). In Assumption 3.3, we take \(x_{t_{i}} = g_{t_{i}}\), \(d\mu = dg\), \(y_{t_{i}} = x_{t_{i}}\) and check that conditions (1)–(4) are satisfied. In Lemma 3.4, we take \(G(u,g) = \sum_{l=1}^{n} \beta_{l}(u)\langle g_{e_{0}}, e_{l}\rangle h_{i}(g)\). Since the functions \(h_{i}: G \to \mathbb{R}\) are smooth and \(G\) is compact, also \(\beta_{l}\) are smooth and bounded by construction, we may apply Lemma 3.4. If \(\phi\) is a bounded real valued continuous function on \(C([0,r]; OM)\), let \(\xi = \phi(x_{u_{\varepsilon}}, 0 \leq u \leq r)\). Then

\[
\lim_{\varepsilon \to 0} E\left( \xi \sum_{l=1}^{n} \int_{0}^{r} \beta_{l}(x_{s_{\varepsilon}}) \langle g_{s_{\varepsilon}}, e_{l}\rangle h_{i}(g_{s_{\varepsilon}}) ds \right)
\]

\[
= \sum_{l=1}^{n} E\left( \xi \int_{0}^{t_{\varepsilon}} \beta_{l}(\bar{y}_{s}) ds \right) \int_{G} \langle g_{e_{0}}, e_{l}\rangle h_{i}(g) dg
\]

\[
= \sum_{l=1}^{n} E\left( \xi \int_{0}^{t_{\varepsilon}} \nabla DF_{\bar{y}_{s}}(H_{\bar{y}_{s}}(e_{l}), H_{\bar{y}_{s}}(e_{l})) ds \right) \int_{G} \langle g_{e_{0}}, e_{l}\rangle h_{i}(g) dg
\]

\[
= \sum_{l=1}^{n} E\left( \xi \int_{0}^{t_{\varepsilon}} \nabla DF_{\bar{y}_{s}}(H_{\bar{y}_{s}}(g_{e_{0}}), H_{\bar{y}_{s}}(e_{l})) h_{i}(g) dg \right).
\]

By the same reasoning, we also have

\[
\lim_{\varepsilon \to 0} \varepsilon E\left( \xi \int_{0}^{t_{\varepsilon}} (DF)_{\bar{x}_{s}}(H_{\bar{x}_{s}}(e_{l})) L_{g_{s_{\varepsilon}}} h_{i}(g_{s_{\varepsilon}}) ds \right)
\]

\[
= E\left( \xi \int_{0}^{t_{\varepsilon}} (DF)_{\bar{x}_{s}}(H_{\bar{x}_{s}}(e_{l}) ds \int_{G} L_{g} h_{i}(g) dg \right).
\]

We have proved (4.2). Since every sub-sequence of \(\tilde{P}_{x_{\varepsilon}}\) has a sub-sequence that converges to the same limit, we have proved \(\tilde{P}_{x_{\varepsilon}} \to \tilde{P}\) weakly.

Finally, we compute the limiting Markov generator \(\tilde{L}\). We observe that there is a family of eigenfunctions of the Laplacian on \(G\) with eigenvalue
Indeed, since \( \sum_{k=1}^{n(n-1)/2} (A_k)^2 = -\frac{n-1}{2} I \),

\[
\sum_{k=1}^{n(n-1)/2} L_gA_k L_gA_k \left( -\frac{4}{n-1} \langle ge_0, e_i \rangle \right) = -\frac{4}{n-1} \sum_{k=1}^{n(n-1)/2} \langle g(A_k)^2 e_0, e_i \rangle \\
= 2 \langle ge_0, e_i \rangle.
\]

Thus,

\[
h_i = -\frac{4}{n-1} \langle ge_0, e_i \rangle
\]

is the solution to the Poisson equation \( (3.3) \):

\[
\mathcal{L}_G h_i = \langle ge_0, e_i \rangle \quad \text{where} \quad \mathcal{L}_G = \frac{1}{2} \sum_{k=1}^{n(n-1)/2} L_gA_k L_gA_k.
\]

We compute the second integral in \( (4.1) \). Since \( L_gA h_i = -\frac{4}{n-1} \langle g\bar{A}e_0, e_i \rangle \), we have

\[
\sum_{i=1}^{n} \int_G (DF)_u(H_u e_i) L_gA h_i(g) \, dg \\
= -\frac{4}{n-1} \int_G (DF)_u(H_u g\bar{A}e_0) \, dg \\
= -\frac{4}{n-1} (DF)_u \left( H_u \left( \int_G g\bar{A}e_0 \, dg \right) \right) = 0.
\]

Consequently,

\[
\bar{\mathcal{L}} F = -\sum_{i=1}^{n} \int_G (\nabla DF)_u(H_u(g e_0), H_u(e_i)) h_i(g) \, dg \\
= -\sum_{i,j=1}^{n} \int_G (\nabla DF)_u(H_u(e_j), H_u(e_i)) \langle ge_0, e_j \rangle h_i(g) \, dg.
\]

In the last step, we use the fact that \( H_u(\cdot) \) is linear and that \( \{ e_i \} \) is an o.n.b. of \( \mathbb{R}^n \). Let us define

\[
a_{i,j}(e_0) = -\int_G \langle ge_0, e_j \rangle h_i(g) \, dg \\
= \frac{4}{n-1} \int_G \langle ge_0, e_j \rangle \langle ge_0, e_i \rangle \, dg.
\]

Then

\[
(4.4) \quad \bar{\mathcal{L}} F = -\sum_{i,j=1}^{n} a_{i,j}(\nabla DF)_u(H_u(e_j), H_u(e_i)).
\]
To further identify the limit, we first prove that $a_{i,j}(e_0)$ is independent of $e_0$. Recall that $G$ acts transitively on the unit sphere of $\mathbb{R}^n$. Let $e'_0 \in \mathbb{R}^n$ we take $O$ such that $Oe'_0 = e_0$. By the right invariant property of the Haar measure,

$$\int_G \langle ge'_0, e_j \rangle \langle ge'_0, e_i \rangle \, dg = \int_G \langle gOe_0, e_j \rangle \langle gOe_0, e_i \rangle \, dg = \int_G \langle ge_0, e_j \rangle \langle ge_0, e_i \rangle \, dg.$$

We first compute the case of $i \neq j$ and $n = 2$:

$$a_{1,2}(e_1) = \int_{SO(2)} \langle ge_1, e_1 \rangle \langle ge_1, e_2 \rangle \, dg = -\int_0^{2\pi} \cos(\theta) \sin(\theta) \, d\theta = 0.$$

If $n > 2$, for any $i \neq j$, there is an orientation preserving rotation matrix $O$ such that $Oe_i = -e_i$ and $Oe_j = e_j$. For example, if $i = 1, j = 2$, we take $O = (-e_1, e_2, -e_3, e_4, \ldots, e_n)$. So

$$\int_G \langle ge_0, e_j \rangle \langle ge_0, e_i \rangle \, dg = -\int_G \langle ge_0, Oe_j \rangle \langle ge_0, Oe_i \rangle \, dg = -\int_G \langle ge_0, e_j \rangle \langle ge_0, e_i \rangle \, dg.$$

Thus, $a_{i,j} = 0$ if $i \neq j$. Let

$$C_i = \int_G \langle ge_0, e_i \rangle^2 \, dg.$$

For $i = 1, \ldots, n$, $C_i = \int_G \langle ge_0, e_i \rangle^2 \, dg$ is independent of $i$ and

$$\int_G \sum_{i=1}^n \langle ge_0, e_i \rangle^2 \, dg = 1$$

and consequently $C_i = \frac{1}{n}$. The nonzero values of $(a_{i,j})$ are

$$a_{i,i} = -\int_G \langle ge_0, e_i \rangle h_i(g) \, dg = \frac{4}{n-1} \int_G \langle ge_0, e_i \rangle^2 \, dg = \frac{4}{(n-1)n}.$$

By the definition, $\Delta_H F(u) = \sum_{i=1}^n L_{H(e_i)}L_{H(e_i)} F$. Since $\nabla$ is the canonical flat connection, $\nabla_{H(e_i)} H(e_i) = 0$. See the paragraph before equation (3.4). By (4.4), we see that

$$\mathcal{L} F(u) = -\sum_{i,j=1}^n a_{i,j}(\nabla DF)_u(H_u(e_j), H_u(e_i))$$

$$= \frac{4}{(n-1)n} \sum_{i=1}^n (\nabla DF)_u(H_u(e_i), H_u(e_i))$$

$$= \frac{4}{(n-1)n} \Delta_H F(u).$$
We conclude that \((\tilde{x}_{t/\varepsilon}^{\varepsilon})\) is a diffusion process with infinitesimal generator 
\[ 4 \frac{(n-1)n}{(n-1)n} \Delta_H. \]
Since \((x_{t/\varepsilon}^{\varepsilon})\) is the projection of \((\tilde{x}_{t/\varepsilon}^{\varepsilon})\) it is also convergent. The 
operators \(\Delta_H\) and \(\Delta\) are intertwined by \(\pi\); for \(f : M \to \mathbb{R}\) smooth, \((\Delta_H f) \circ \pi = \Delta(f \circ \pi)\). See, for example, Theorem 4C of Chapter II in Elworthy [6] and 
also Elworthy, Le Jan and Li [7]; \(\Delta_H\) is cohesive and a horizontal operator 
in the terminology of [7] and is the horizontal lift of \(\Delta\). We see that \((x_{t/\varepsilon}^{\varepsilon})\) converges to a process with generator 
\[ 4 \frac{(n-1)n}{(n-1)n} \Delta \] where \(\Delta\) is the Laplacian on the 
Riemannian manifold \(M\). We have completed the proof of Theorem 1.1.

\[ \square \]
